PREFACE

THE AUDIENCE

This book is directed to Federal libraries and the librarians who staff them. The main audience will be library administrators; middle-level managers and section heads also will benefit from this material. Parts of the book also may be of value for staff training late in the development of minicomputer projects.

The library director, as the decisionmaker, should be familiar with minicomputers and their applications in libraries. After deciding to use minicomputers, the director must either direct the project personally or assign a project director.

> The qualifications required for successful project direction are not rigid. However, the following characteristics are very important:
>
> - Ability to communicate well
> - Sound knowledge of library operations
> - Familiarity with at least basic fundamentals of data processing technology
> - Ability to write clearly
> - Sound constitution and steady nerves.[1]

The project will probably involve a systems team that includes data processing experts experienced with hardware, systems analysis, and programming. The team may draw from agency personnel or from outside contractors. Whichever procedure is used, the librarian must be a working member of the team and must control the major decisions. It is the intent of this book to prepare librarians for this role.

The entire staff should be kept informed of the progress of the automation effort because their high morale and support of the system are vital to the success of the project. Lack of knowledge often prompts fear of the unknown. In addition to constant communication, the staff should receive training, at least in the form of general orientation to library automation and minicomputers.

In fact the library staff should play an integral part as contributors to the development of the system. The library director alone cannot give the necessary detailed input to the system designers. It has b pointed out that often only the staff are "in a posit to recognize a serious flaw in an operating procedu Unless they have been given the opportunity to what the purposes are, they can hardly begin to br out what would otherwise be only intuitive feeli that 'something's not right'."[2] To participate fully a meaningfully, the staff may have to be trained or least briefed on systems analysis, library automati and minicomputers.

THE SCOPE

This book covers the application of minicomput in Federal libraries. The first four chapters, Par form a general textbook treatment of automati library automation, minicomputers, and library ap cations of minicomputers. In Part II, Chapters 5 and guidelines for selecting and implementing a minico puter system are presented.

The chapters of Part I provide the necess background for reviewing library needs and mak decisions in applying minicomputer technology. If reader is already familiar with automation a minicomputers, he or she may begin at Part II. depth explanations of computer technology are possible in this book, and are, indeed, unnecessary most of the librarians who will read this book.

An understanding of systems analysis is importan the readers of this book but is not covered in de here. The library director making the decisions applying minicomputers should have completed initial stages of systems analysis before applying guidelines in this book. The director may foll *Guidelines for Library Automation,*[3] sponsored by Federal Library Committee, for a thorough treatm of library systems analysis directed specifically Federal libraries.

TIMELINESS

The time for minicomputers in libraries has come. The *Annual Review of Information Science and Technology*[4] had a chapter on minicomputers for the first time in 1975. The September 1976 issue of *Library Technology Reports*[5] featured a description of three commercial library systems that use minicomputers. There is a need for this book, though some sections may be out of date before it is published. This is true of any work that deals with specific makes and models of equipment. In this case, the problem is compounded by the state of minicomputer technology. This infant area is just beginning to mushroom and grow. Changes in basic methodologies or breakthroughs in techniques can occur at any moment and drastically change capabilities and applications. It is all for the better, but one is warned to stay on top of this dynamic field.

THE SPONSORS

The Federal Library Committee (FLC) has recognized the trend to minicomputer applications in libraries and their value to Federal libraries. In response FLC has organized a working group on minicomputers to serve as a forum for Federal librarians to share knowledge and experience; FLC also contracted with Informatics Inc. to write this book. The Library Information Services section of Informatics Inc.'s Information Services Gro singularly qualified to perform this task. Unde administration of Jack A. Speer, Director, Li Information Services has supplied library tecl services for a number of Federal libraries, incl acquisitions services, feasibility and design studie production of bibliographic products. It has developed a commercial minicomputer syste support cataloging.

Dr. Micki Jo Young was selected by Mr. Sp write the book. The background of Dr. Young in expertise in library technical services manage large-scale computer systems; minicomputers cataloging utility tool; and systems design. Fra Pezzanite and J. Chris Reisinger of Informatics' staff provided technical expertise for this book Pezzanite is the Technical Director of Library mation Services and was in charge of project de ment for MINI-MARC, the firm's commercial computer module for cataloging. Mr. Reisin Technical Director for Electronic Composition S es in the Information Processing Services Divisio is responsible for computer-based text-proce using both large-scale computer systems and min puter systems. Together, these three persons b well-rounded professional view of minicomput Federal library applications.

June

CHAPTER ONE

OVERVIEW OF AUTOMATION

HOW A COMPUTER WORKS

In general there are three possible modes for library operations: manual, mechanized, and automated. At one time all catalog cards were written by hand, and penmanship called library hand was taught in library school. The typewriter, and then multilith, offset, and photocopy processes mechanized card production. The next step, automation, involves use of a computer.

Ned Chapin defined the computer as follows: "An automatic computer is a machine that manipulates symbols in accordance with given rules, in a predetermined and self-directed manner."[1] The key word is "self-directed." This is what distinguishes automation from mechanization. Sometimes this concept is called the "stored program." Cox, Dews, and Dolby wrote, "A librarian interested in the potential usefulness of a computer must first have an idea of what the machinery and associated programs can do."[2] It is for this purpose that the following general description of computers, their functions and roles, is presented.[3]

There are two main types of computers: analog and digital.[4] An analog computer represents variables by analogies. That is, it represents numerical quantities by means of physical variables such as translation, rotation, voltage, or resistance. Analog computers are used mainly in industry and for scientific applications requiring simulation of nature or natural properties. A digital computer expresses variables in discrete, countable form usually by means of coded characters such as numbers, signs, or symbols. Digital computers are best suited to arithmetic and logical operations in and engineering applications. Because of the library operations, digital computers are us sively for library automation and the r discussion will deal with digital computers onl

To understand computers, one must consi the equipment (hardware) and the instru programs that make them self-directing (softw

HARDWARE

Five separate functions can be performed puter hardware:[5]

- *Conversion* from one form of represent another
- *Storage* for varying periods of time
- *Communication* by movement of data
- *Logical* and arithmetic *processing*
- *Display* in human-sensible form.

No one machine performs all five functions a number of devices are combined. The components required to perform the five consists of:[6]

- An *input* unit
- The *memory*
- The *control* unit
- The *arithmetic* unit
- An *output* unit.

Each of these components is not nece separate piece of equipment. Some compon multiple uses (e.g., both input and output) c

more than one unit in one device. Also, under any one category there is a variety of devices from which to choose. For example, there are several types of input units: punched card readers, paper tape readers, optical character recognition devices, and key-to-disk stations, among others.

Central Processing Unit

The central processing unit (CPU) is the heart of the computer. It combines two of the five main functions; it is composed of the arithmetic and the control units and is closely tied to the main memory.

In a digital computer the main units of computation are discrete, countable codes, most commonly numbers. Even more basic than number codes is the simple on-off distinction. This is the principle on which digital computer operation is based. The on and off states are represented numerically by 0 and 1.

0 (zero) = "off"
1 (one) = "on"

In digital computers arithmetic computations and numerical expressions are based on this binary (base-two) number system rather than the decimal system because binary is easier to manipulate by computer.

Figure 1 shows a simple comparison of the binary and decimal number systems. Further references are recommended for additional study of binary mathematics.[7] At this point the thing to remember is that the 0–1/off-on condition is the basis of all computer operations. The instructions or commands of the program that allow the computer to be "self-directed" are represented by 0–1 codes, as are the data to be processed or manipulated.

There are several standard 0–1 codes in which separate arithmetic values are used to represent specific letters, numbers, or symbols. Some codes have been standardized throughout the computer industry and can be used on any manufacturer's equipment: BCD, EBCDIC, and ASCII are the three most common. ASCII (American Standard Code for Information Interchange) is used throughout the Federal Government as the standard and is the code for the Library of Congress MARC II distribution tapes.

Table 1 gives the seven-digit (seven-bit) binary pattern for each letter, number, and symbol in the

binary (arithmetic) values in ascending num order; if data expressed in ASCII code is sort numerical order, it will result in this sequ Programmers often review and manipulate da binary form as programs are developed and corre Representing each character with seven digits be cumbersome and slow. To provide a short method of handling these binary patterns, hexa mal notation is sometimes used. Hexadecimal base-16 system in which there are 15 decimal before the 10 (no units, one 16) is reached. Be there aren't enough numerals to express all the the letters A through F are used:[8]

TABLE 1—Comparison of Decimal, Hexadecim and Binary Systems

Decimal System	Hexadecimal System	Binary System 8 4 2 1 bit valu
0	0	0 0 0 0
1	1	0 0 0 1
2	2	0 0 1 0
3	3	0 0 1 1
4	4	0 1 0 0
5	5	0 1 0 1
6	6	0 1 1 0
7	7	0 1 1 1
8	8	1 0 0 0
9	9	1 0 0 1
10	A	1 0 1 0
11	B	1 0 1 1
12	C	1 1 0 0
13	D	1 1 0 1
14	E	1 1 1 0
15	F	1 1 1 1

When hexadecimal notation is used for ASCII every four bits are represented by a hexade character. Since ASCII is a seven-bit code, the e bit (reading from right to left) is assumed always zero:

ASCII	G =	_1000111	= Hex 4
Hex		0111	= 7
Hex		0100	= 4
ASCII	k =	_1101011	= Hex 6
		6 B	

This allows eight characters to be reduced to characters for efficiency, but it must be rememl

memory and are actually manipulated. Table 2 gives the hexadecimal notation for each ASCII code.[9]

The arithmetic unit is where the manipulation of the data occurs.[10] Whether the original data were figures or words, the binary codes are manipulated by arithmetic or pseudo-arithmetic operations. The on-off combinations of the electronic impulses are called circuit elements and represent combinations of the basic logical operations AND, OR, and NOT.[11] These circuit elements allow binary numbers to be added, subtracted, multiplied, divided, and compared. Figure 2 shows several circuit elements, and the logical operations they represent.[12]

The instructions or program give detailed commands that control the pattern and sequence of the circuit elements. These must be explicit to the last detail; the computer is not an electronic brain but rather an electronic slave.[13] The impact of this detail will be discussed in the section on software.

Four main classes of computer instructions are carried out by the CPU:[14]

1. *Arithmetic and logical instructions.* These instructions add numbers together, compare patterns of letters or numbers, reorganize the coding of characters, etc. [Sometimes this class is divided into two classes, one strictly for arithmetic, and the other for logical operations.]
2. *Fetch and store instructions.* These instructions are used for moving information about in the memory or store.

C = 1
If A = 1, C = 0
If A = 0, C = 1

3. *Jump [or branch] instructions.* These instructions allow the sequence of operations to vary according to the data being examined.
4. *Input and output instructions.* These instructions are used to fetch blocks of information into the memory from input units and send information from the memory to output devices.

The actual data or codes manipulated by the arithmetic and logic unit are generally held in that unit in a register. A register is a semiconductor device of electromechanical flip-flop switches that holds the data.[15] The register is where the actual operations on the data are performed, such as analyzing, shifting, and performing arithmetic on the numbers in the register.[16] Usually there are multiple registers, and these can be called accumulators. A register has a fixed size and is referred to by name, not by its location in the memory.

The control unit in the CPU handles the switching and flow of the instructions and data in the CPU and in the computer as a whole. It sets the sequence of operations, decodes instructions, and provides the control signals to coordinate the various units of the computer.[17] At a simplistic level the data represented as a pattern of on-off electronic impulses travel through a series of circuits or gates that alters the flow and thus the patterns of the impulses. The circuits or gates are chosen according to the operation to be performed.

The control unit regulates the flow of impulses and the setting of the gates in response to the instructions in the proper order. There are two main registers in the control unit: the instruction register and the location counter. The control operates in cycles. The basic cycles are (1) the instruction cycle (I-time), during which the instruction register receives the next instruction in the program from the main memory, the instruction is interpreted into circuits, and the location counter receives the address of the next instruction, and (2) the execution cycle (E-time) during which the instruction is performed.[18]

Memory

The memory stores information, received through an input unit or developed during the processing of

without being destroyed.[19] There are two kin memory or storage. One is main memory, also c working storage or internal storage, and the otl mass storage or auxiliary memory.

The main memory is closely related to the arit tic and control units. It is sometimes considered p the central processing unit or mainframe (see F 8). The main memory holds the data manipulat the arithmetic unit. Because of the speed of proce the data must be readily available, so they are m from mass storage into main memory. The data instructions are given unique addresses, or loca The instructions include the address of the data manipulated as well as the address of the instruction. The computer, thus, is self-directing. few processors, arithmetic and logic operation performed directly on the data in the main mer In general, however, data are moved from the memory to a register in either the arithmetic and unit (for data) or the control unit (for instructi

The main memory in most current comput made up of magnetic cores (small rings of a ferro netic material) wired together in an array.[20] Each can hold one binary digit — either zero or one — magnetic state. (The internal memory also is calle core.)

The main memory is described in two ways: in of its addressability and its size. At the lowest le single binary code (either one or zero) is called a *b* express logical characters such as a number or a l several bits are grouped in a unit called a *byte.* A has a fixed length depending on the hardware de six-bit and eight-bit bytes are common. The sm addressable unit in internal memory is called a Words can be made up of from one to eight depending on the manufacturer's design.

The capacity of the main memory is express terms of the number of addressable units it can either words or bytes. Capacities are express thousands (K); common capacities are 4K, 8K, and 32K. With the unit addressability added memory is expressed as 4K words, 16K bytes, or bytes (which can be the same as 8K words if the are 4 bytes or 32 bits each).

Auxiliary or mass storage is used to retain

chine-readable form. The storage medium can vary. The storage may be in mechanical, electronic, or magnetic form. The standard punch card is a common mechanical storage medium. Electronic storage is now generally limited to storage during transportation, e.g., telecommunications. Magnetic storage is most common and uses tapes, disks, drums, or strips.

Mass storage data generally are organized in files. There is a hierarchy of data.[21]

Bit: a single binary digit, either 0 or 1.

Byte: a group of bits (usually eight) that represents a logical character such as a letter, number, or symbol.

Field: characters combined into logical units or data elements. Fields can be divided into subfields if appropriate to the intellectual content of the data. For example,

Field — personal name
Subfield 1 — last name
Subfield 2 — first name and middle initial.

Fields can be defined by the programmer as fixed-length (always n number of characters) or variable-length (as many characters as necessary to express the logical unit).

Record: related fields combined into a complete, logical unit.

File: like records combined for the system.

Data base: a group of files related to a system application.

The order of the records in the file and therefore in the main memory device is called file organization. Available methods of file organization include[22]

1. *Sequential (continuous allocation).* The records occur in a linear order sequenced usually by a control number (Figure 3a). To update the file by adding or deleting a record, a new sequence would have to be compiled. For example, deleting #2341 and adding #2350 would produce something like Figure 3b.

2. *Linked (linked list allocation).* The records do not occur in any order on the file, but the address of the next logical record is carried in the record to link the two together (Figure 4a). To update the file by adding or deleting a record, one need modify only the address of the next record or re-link the records. For example, deleting #2341 and adding #2350 would produce a file like that shown in Figure 4b.

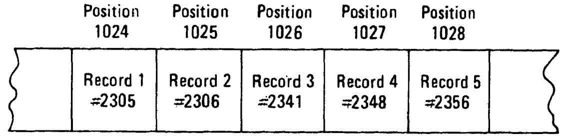

FIGURE 3.a. Records in a sequential file structure

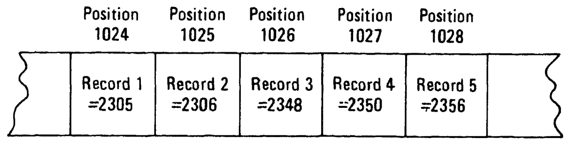

FIGURE 3.b. Updated record sequence

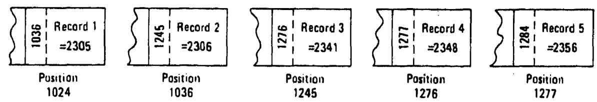

FIGURE 4.a. Records in a linked file structure

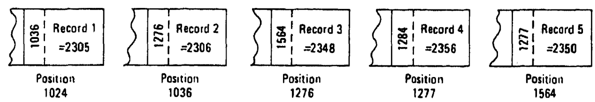

FIGURE 4.b. Updated file

3. *Indexed Sequential.* The records are stored sequentially in units, or blocks, and the locations of key records are entered in an index (Figure 5). This index shortens the time required to locate a record. With the methods described above, each record had to be scanned or read either to match the control number or to read the address of the link. With index sequential organization the index is scanned by a key, and a pointer is given to the area of the file where the record is located. The computer then reads only those records in the unit or range. To allow convenient addition of new records, space is usually left in the file at various points.[23] On multiplatter disks, the block or unit where

FIGURE 7. Two-dimensional depiction of a direct access file structure

The physical arrangement of the data on the medium, the form they take, the speed with which they can be accessed, and the storage capacity all var these factors must be considered when a con configuration is being assembled.

Input

In the discussions of manipulation and stor data so far, data have been described as bei binary (on-off) or machine-readable form. A who wishes the data to be processed begins information in its "natural," original form. information is human-readable and is generally the source document. The information mu converted to machine-readable form, and this accomplished via an input device. Two process involved: converting the human symbol into co converting the code into electronic impulses.

Numerous techniques are used, and many pi equipment are available. Some require a two- or stage conversion, and others allow direct Punched holes in cards or paper tape are "read machine that allows current to flow wherever th hole, giving an "on" or "one" impulse. Magneti used and "read" by machine to produce impu light pen can be used to "read" a bar code; th are used to produce impulse patterns. Optical c ter recognition is more complicated, but it is sim the light-pen system. The lines of the charact "read" onto a matrix and the resulting patt compared to a reference table; when a match is the impulses for that character are created.

A human symbol, a letter or number, must as an electronic impulse in the binary, on-off sch the computer. Most input devices allow the pe use human symbols and then convert the syml machine-readable codes and ultimately to im The initial input device used is often offlin independent (standalone), like a keypunch ma The converted data it produces can be "reac added to the computer storage as desired.

Output

Just as source data must be converted to ma readable form to be manipulated by the CPU, the processed data must be converted to h sensible form to be meaningful to the system u most cases only a portion of the data in the sy needed at any one time. The output must be sel

[24] Eckhouse, *Minicomputer Systems*, p. 229.
[25] R[ichard] T. Kimber, *Automation in Libraries*, 2d ed. (Oxford: Pergamon Press, 1974), pp. 50–51.

formated as required, and expressed in a suitable medium. The output is also called a "display."[26] Most displays are visual and in a printed form (although computers can produce oral responses). The most common is the printout on continuous-form paper, printed on a fast, computer-driven printer. Photocomposition is possible as an output. A computer tape is produced that is formated and ready to use in an automatic typesetting machine like the Government Printing Office's Linotron. Computer-output microforms (COM) are also a form of printed display. "Soft" displays are produced on a cathode-ray tube like a television screen. This gives the user human-sensible data immediately but leaves no permanent record of the data.

The Configuration

The input, output, and storage units, together with the central processing unit, combine to form the computer hardware system or configuration. In the literature, systems are described in various ways. Some sources show the entire system as "the computer"; others call only the central processing unit the computer and all the other devices peripherals. The CPU, encompassing the arithmetic and logic unit, the control unit, and main memory, is also called the mainframe. The block diagrams in Figure 8 represent some common depictions of computer configuration.[27] However the computer is depicted, the system is operated by the CPU, specifically the control unit.

The connection of these units and their interfacing can be very complicated and involve both hardware and software control. The speed of operation of the several units can vary within one system. A card reader may input 80 characters of data at a much slower rate than a tape drive can read them; one printer may print 300 lines per minute, while another operates at 1250 lines per minute. Some devices are farther removed physically from the CPU than others, and the time required for their electrical impulses to travel is greater. Some processing operations take longer than others. The control unit must consider all these elements and must sequence and time the impulses and events accordingly.

To the human, the speed of the CPU is so great that operations may seem to occur simultaneously. This is not true, however; the computer operates in one-step-at-a-time manner. The CPU inst input/output controller to read or write info and the I/O controller performs the actual tr data between internal memory and the p devices. There actually may be several I/O c in a system, each suited to a particular input/output device. Sometimes the control integral part of the input/output device. A often used as part of the interface. It is a temporarily storing data until they are need buffer storage can be designated as part of memory or as part of the controller. In interface physically connects the units of the ration and serves to compensate for differenc speed of data flow, in the timing of the mov data from one device to another, and in the codes or formats involved.

SOFTWARE: COMPUTER PROG

A computer is directed to manipulate data predefined sequences of instructions called *p* Computer instructions at their most fundame are expressed in binary codes and are referred machine's language.

Machine language is extremely crude (lo tic), and it is difficult and time-consuming to late. To ease the burden of program pre special programs are provided to allow hu express problem solutions in functional terms object of constructing the machine language to implement the program. These special prog called assemblers, compilers, or interpreters, statements one codes to express problem solu themselves called programming languages. S gramming languages are very close to t computer's own language and are suited for on that computer. These are called assembly es. Other programming languages are stru express a problem's solution in human or nea language. These are the compilers and in and are called high-level programming l COBOL, FORTRAN, and BASIC are a most commonly used high-level languages. H languages have the advantages of ease of development and machine independence; a

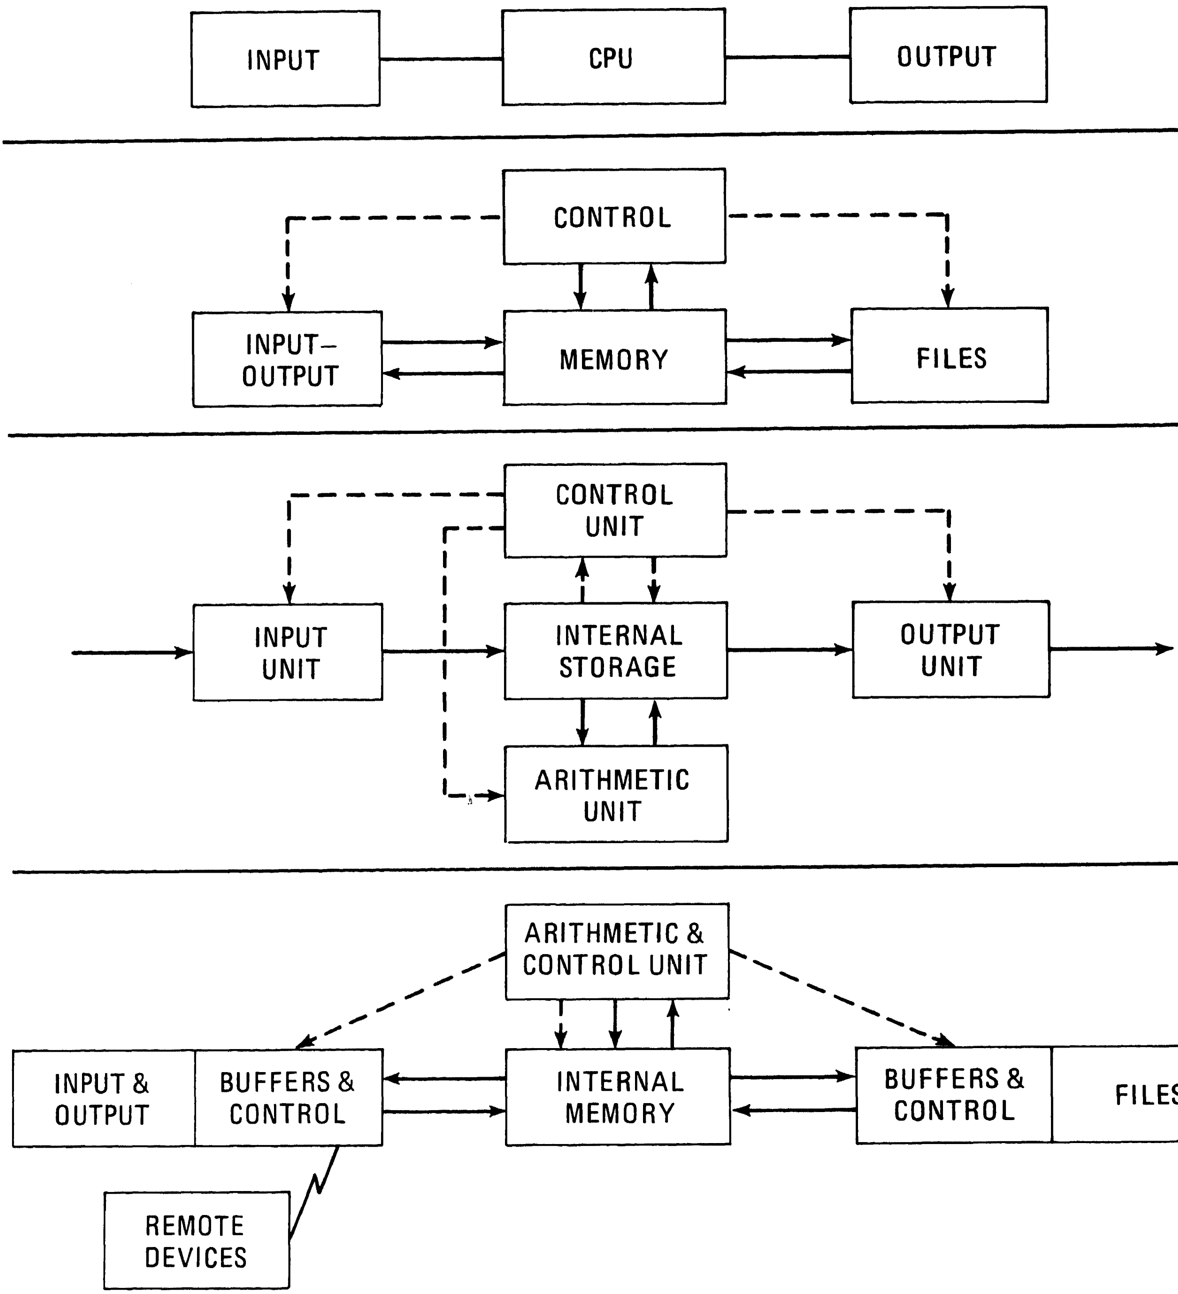

FIGURE 8. Sample block diagrams of a basic computer configuration

written in one of the high-level languages may be run on any computer having a compiler or interpreter for that language.

In preparing a computer program, the objective must be defined and the procedure to accomplish the objective established. These items usually are expressed in a flow chart. Using the flow chart, the steps to be followed to accomplish the objective can be expressed graphically. Some procedures are simple linear paths (Figure 9). Some call for branch logic

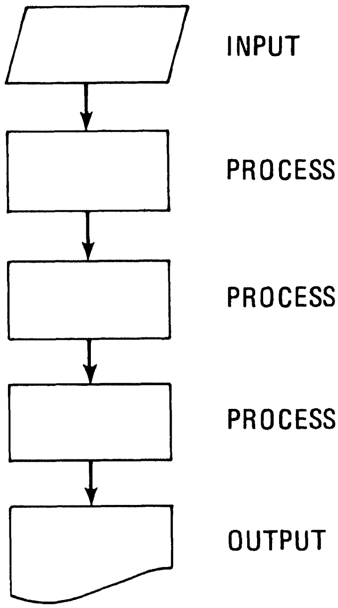

FIGURE 9. Simple linear path flow chart

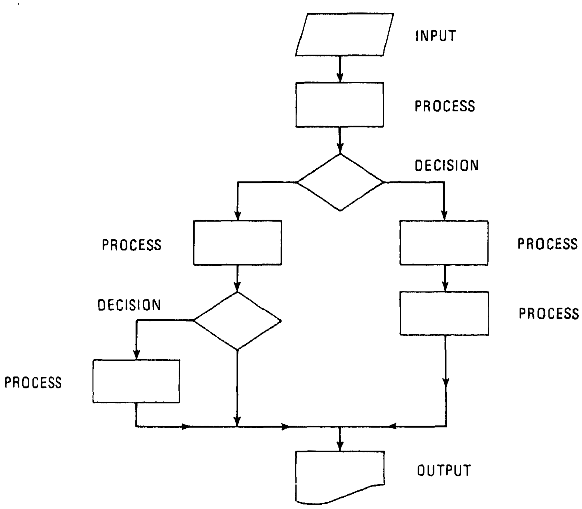

FIGURE 10. Branched logic paths flow chart

based on decisions (Figure 10). Some require
steps, accomplished by using a loop (Figure 1

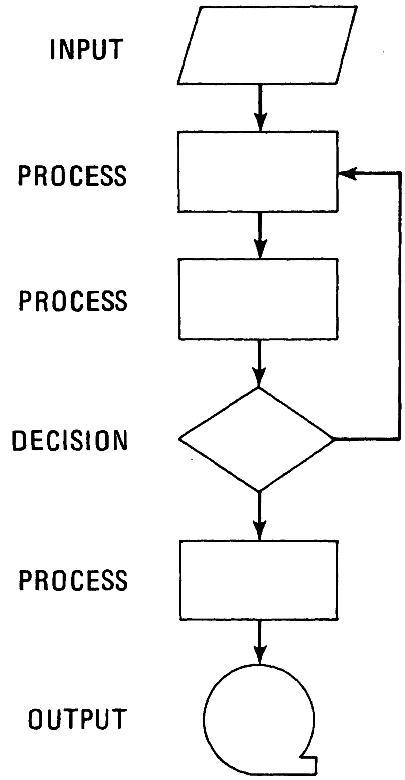

FIGURE 11. Loop flow chart

The more complicated the procedure the m
plex the flow chart (Figure 12).[29]

Through a series of flow charts, each mor
and detailed, the procedure finally is reduc
elementary steps in the proper sequence. T
flow chart is what is expressed in the ter
programming language. Several routine
must be considered with every program; t
depends on the conventions of the prog
language used.

Whether it is written in assembly or l
language, a program must ultimately b
machine's language. Computers understand
of instructions.

- Input/output instructions
- Internal data movement instructions
- Arithmetic instructions
- Testing and comparison instructions
- Jumping or branching instructions.

[29] Heiliger and Henderson, *Library Automation*, p. 205.

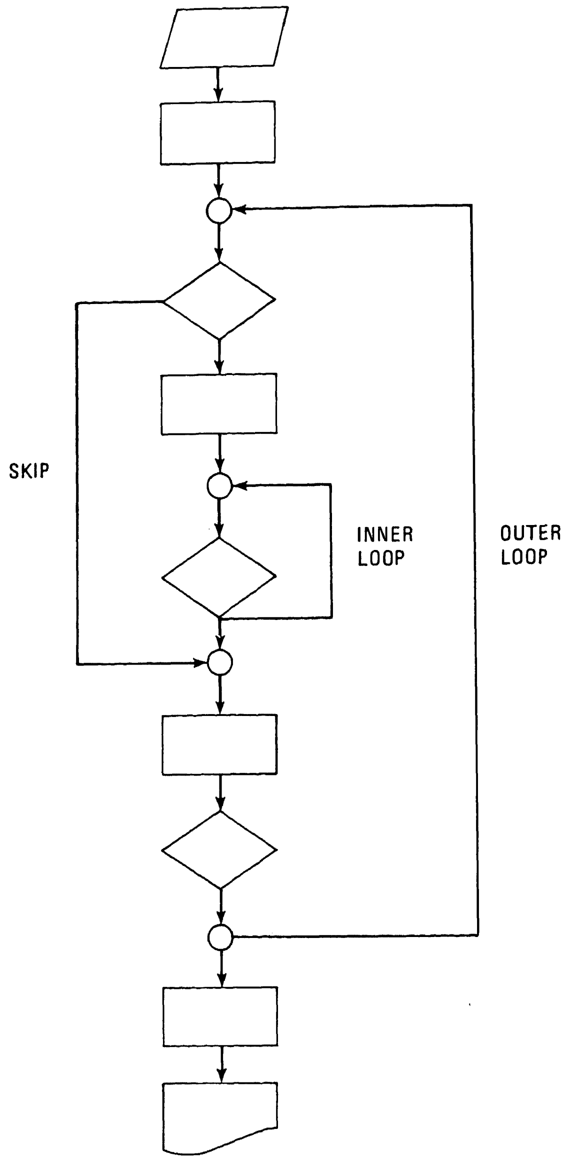

FIGURE 12. Repetitive loops flow chart

The number and power of instructions in each category vary significantly from one computer to another. While one computer may understand 20 arithmetic instructions, another may understand only 2. The complete set of instructions in each category plays a major role in the suitability of a computer for a particular application.

The basic structure of a computer instruction is as shown in Figure 13. The *op* part of a computer instruction defines the operation to be performed, and the address(es) part defines the memory location o data to be manipulated. Some operations may req a single address, and others may require two or n

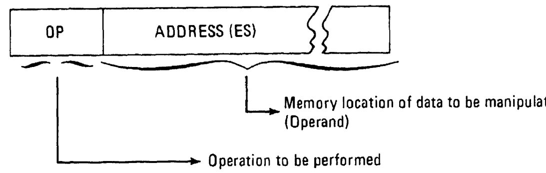

FIGURE 13. Basic structure of computer instructi

Instruction addresses in some computers ma expressed in terms of the sum of two or more va Typically these types of addresses cause the conte the address portion to be incremented or decreme by one or more special machine accumulators c index or general registers. Still other comp provide for specification of an address that locate the data to be manipulated but rather the addr the data. This feature is called an indirect ad Thus a computer instruction address may appear Figure 14.

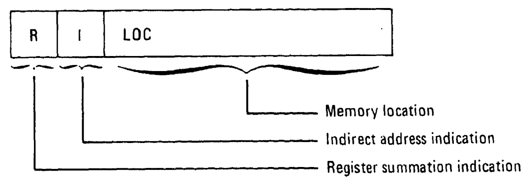

FIGURE 14. Address portion of a computer instru using the indirect addressing technique

Some computers have no provision for *R* or *I* others provide for only one or the other. If n indexing nor indirect addressing is provided, prog ming can be very difficult indeed.

In high-level programming languages the abil the computer to index or indirectly address is portant to the programmer because the high language requests functional operations rather detailed machine-level instructions. The compil interpreter produces the code required to perfor requested functions, based on the capabilities limitations of the computer for which it compi interprets.

Certain computer instructions cause activity must be communicated to the program. As an ple, a data input instruction should communic the program whether or not an error has occ during the reading of data. Thus, computers gen maintain a special internal status indicator call condition code. Usually the condition code is onl bits long, and each bit indicates a special con

based on the last instruction executed. Table 3 illustrates the meaning of the bits of the condition code based on representative instructions.

TABLE 3—Breakdown of Condition Codes for Representative Instructions

	Condition Code			
Instruction	**Bit 0**	**Bit 1**	**Bit 2**	**Bit 3**
Input	End of file	Error		
Output	End of Media	Error		
Compare	A = B	A B	A B	
Add	Result 0	Result +	Result −	Overflow
Subtract	Result 0	Result +	Result −	

In machine-level or assembly language the condition code may be tested following an instruction, and the sequence of executing instructions may be altered as a result. The condition code is not apparent to the high-level programmer because the functional statements make no specific reference to it.

Input/Output Instructions

Data are transferred between memory and I/O devices through specially designed I/O instructions. Machine language and/or assembler language programming can become very difficult in this area unless the programmer has access to preprogrammed routines that perform these functions. Most I/O processes require that the operation go through the following phases:

1. Ready the device
2. Start the transfer
3. Wait for completion
4. Verify successful transfer.

Unless preprogrammed routines are available, these processes must be programmed. They can be more difficult to program accurately than the application itself.

High-level languages allow the transfer of data to be specified at a functional level (READ or WRITE), with the compiler or interpreter automatically producing the machine-level code required for all phases of the operation.

Internal Data Movement Instructions

Data may be moved from one memory location to

With high-level languages, instructions data to or from registers are not nece computer makes the transfers automatica fore, high-level languages do not need to these differences. The high-level languag mer need only specify the requirement for and the compiler or interpreter will p machine-level instructions to see that it o thermore, the high-level language progra not be concerned with the fact that some must move data a single character or wor while others may move blocks. Again, the interpreter produces the requisite machine as needed.

Arithmetic Instructions

Arithmetic instructions perform additio tion, multiplication, division, and at ma certain other functions such as changi shifting. Some computers provide special for floating-point operations.

Arithmetic typically is performed in sp signed accumulators or registers (see abov ing) but sometimes may be performed in n modern computers perform binary arith most provide decimal arithmetic or conv one form to the other.

High-level languages allow programme their own accumulators upon which arith tions are to be performed. The compiler or will provide the necessary binary-decimal machine instructions. Further, high-level usually provide statements that define the be solved, including sine, cosine, and s functions. The machine-level solution to ments may be very complex and may requ dozens of individual instructions.

Testing and Comparison Instru

These instructions are used to establish th code reflecting the relationship of one another. At the machine and assembler gramming these instructions would be f conditional jump or branch instructions th sequence of program execution based on th

the IF statements allow construction of AND and OR functions that establish complex relationships to determine processing. Such functions require many separate machine- or assembler-level instructions that successively test and jump.

Jumping or Branching Instructions

Jumping, or branching, instructions are used to alter, conditionally or unconditionally, the sequence of program execution by the CPU. For example, one may follow an instruction to COMPARE with an instruction to JUMP IF EQUAL or JUMP IF HIGH. Unconditional jumps are used to transfer control regardless of the setting of the condition code.

High-level languages usually provide a GO TO type of instruction to perform unconditional changes in processing sequences, but handle conditional changes through IF, THEN, and ELSE instructions.

Programming Example

To illustrate the concepts of programming, consider the problem of converting a two-digit month number

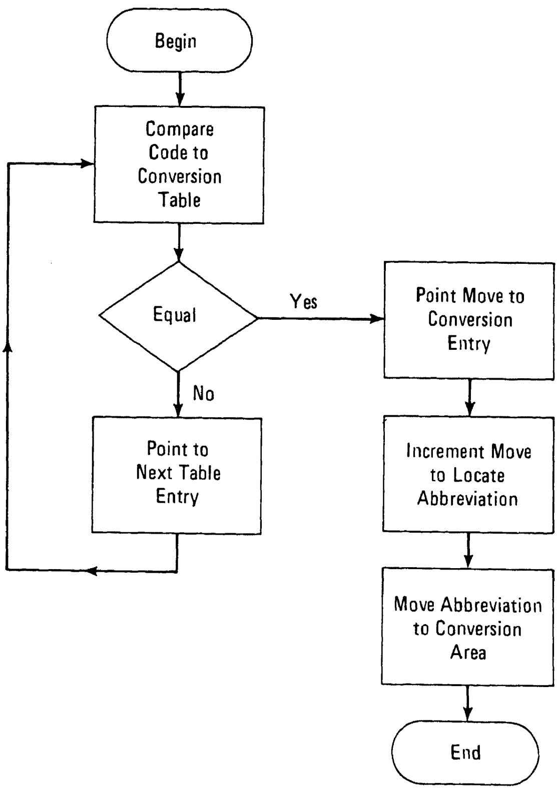

FIGURE 15. Program flow chart of month number to month abbreviation conversion

(01–12) to a three-character abbreviation fc month (Jan–Dec). Program this function usin chine, assembly, and high-level languages. Th guages used are not actual but are representa those available.

Figure 15 is a flow chart of the program in ma language terms. Tables 4 and 5 give the basic ele of this program. The text following explains significance.

TABLE 4—Memory Definition

Memory Location	Data Content	
001	01JAN	TABLE OF MONTHS
006	02FEB	
	.	
	.	
056	12DEC	
061	03	TWO DIGITS FOR CONV SION
063	- - -	OUTPUT OF CONVERSI

TABLE 5—Machine Language Program Eleme

Instruction Number	Memory Location	OP*	Data Length	Address
1	100	CP	02	061
2	110	JE		130
3	115	AD	03	200
4	125	JU		100
5	130	MV	03	107
6	140	AD	03	203
7	150	MV	03	000
	200	005		
	203	002		

*CP = Compare
JE = Jump if equal
AD = Addition
JU = Jump unconditionally
MV = Move data

In this program, memory locations 001–060 c a table of two-digit months with their three-cha abbreviations. Memory locations 061–062 conta two-digit code (03) to be converted, and location 065 are reserved to contain the converted resul instructions begin at location 100, and are per as follows:

1. Compare two positions at 061–062 with th at the address shown (initially 001).
2. Jump if equal to location 130.
3. Add the three-digit code in locations 2((005) to the second address of instruction causing the instruction to compare on th entry in the month table.

. Unconditionally jump to location 100 (the compare instruction as now modified by instruction 3).
. When the appropriate conversion table entry is located, move the second address of instruction 1 (locations 107–109) to the first address in instruction 7. Thus instruction 7 is constructed to point to the month abbreviation table entry.
. Add locations 203–205 (002) to the first address of instruction 7. Thus instruction 7 locates the abbreviation.
. Move the abbreviation to locations 063–065.

embly Language Terms

'able 6 gives the elements of this program in embly language terms.

TABLE 6—Assembly Language Program Elements

eference	Symbol	OP	Address(es)
1	TABLE	DC	'01JAN'
		DC	'02FEB'
		.	
		.	DEFINE MONTH TABLE
		.	
2	INCODE	DC	'12DEC'
3	OUT-CODE	DC	'___' RESULT FIELD
4	LOOP	CP	INCODE(2),TABLE
5		JE	FOUND
6		AD	FIVE(3),LOOP+7
7		JU	LOOP
8	FOUND	MV	LOOP+7(3),LOOP+4
9		AD	TWO,SAVE+4
10	SAVE	MV	0(3),OUTCODE
11	FIVE	DC	'005'
12	TWO	DC	'002'

'his assembly language program parallels the chine language coding required in the first exam-. Notice, however, that the actual memory locations data in the addresses need not be coded. Instead, gn symbolic names to the data the assembly guage program will use to supply the actual mory addresses. Still, one assembler instruction for h machine instruction must be coded, and only tructions that are actually part of the repertoire for computer can be coded. The following explains the gram:

1. The symbol TABLE is assigned to the first entry DC (define characters) for the Month Table. This is followed by eleven other DCs that complete the table.
2. INCODE is the symbol assigned to the characters representing the code to be converted.
3. OUTCODE is the symbol assigned to the result field.
4. LOOP is the symbolic name given to the compare instruction. Note that the instruction is coded using the symbolic names of the fields it acts upon. Also note the (2) defining the length of the fields to be compared.
5. JE alters control if the condition code is set to EQUAL after the comparison. Note the use of the symbolic name FOUND instead of an actual memory address.
6. Here add 5 to the second address of LOOP. These instructions parallel exactly those required by the computer in the machine language example. However, the memory addresses in symbolic terms can be written, using LOOP + 7 to locate the positions to be incremented and FIVE to locate the amount of the addition.
7. Here return to LOOP for continued searching.
8. Match the code in INCODE to one in TABLE, and move the second address of the compare instruction to the first address of the SAVE instruction.
9. Add 2 to the address in SAVE to locate the first of the three characters to be saved.
10. Move the abbreviation to the result area. Note that this instruction is filled in by instructions 8 and 9.

11,12. These are the numeric values needed to perform the additions in instructions 6 and 9.

High-Level Language Terms

Table 7 gives the elements of the program in terms of a high-level language.

TABLE 7—High-Level Language Program Elements

Reference	Commands			
1	MONTH	DEFINE	'03'	MONTH CODE
2	RESULT	DEFINE	'_'	RESULT FIELD
3	TABLE	DEFINE	(2,3)	
			'01JAN'	MONTH TABLE
			'02FEB'	
			.	
			.	
			.	
			'12DEC'	
4	LOOKUP MONTH IN TABLE GIVING RESULT			

Using the high-level language concept this problem can be solved through functionally related statements as follows.

1. Define the month code to be converted.
2. Define the conversion output location.
3. Define the conversion table with the characteristics of two-digit code = three-character output.

4. Specify the conversion by LOOKUP of MONTH IN TABLE GIVING RESULT. That is, the compiler will produce the code necessary to search TABLE and move the located abbreviation to RESULT. The code will be essentially that shown in the Machine Terms example.

OPERATING MODE

In all computer systems the hardware and software work together to perform the functions. However, the way they work together can vary. The system can be batch, remote batch, online interactive, or time-sharing. The facility can be dedicated, shared, or time-shared. These conditions all affect the final outcome or product.

Dedicated, Shared, or Time-Shared

A *dedicated* facility is one used for only one customer or unit.

A *shared* facility serves more than one customer or unit. The computer must be scheduled to meet the various customers' requirements. The equipment configuration, the software, and the staff must be able to meet the requirements of all users, which can be diverse.

A *time-shared* facility is often a commercial service or company in business to serve users on an equal basis. The computer is removed from the user, and access or control is remote. The software is very general and often not suited to special applications.

Batch, Remote Batch, Online Interactive, or Time-Sharing

A *batch* operation is one in which a number of transactions to be processed are accumulated and processed together. Usually they are sorted into sequential order and matched against affected files.[30] In most facilities a computer operator initiates the operation: he calls up the program, mounts the tapes for auxiliary storage, starts the input device, and readies the output device(s). When processing is complete, the operator wraps up the operation and goes on to the next customer's job.

A *remote batch* operation is a combination of online and batch processing. The data are gathered online and held in a queue; then the processing of the data is performed in a batch mode according to a schedule.

In an *online* operation, the input and output u in direct, continuous communication with the processing unit.[31] The data are acquired onl used in conjunction with direct-access files so tl transaction is received by the computer, releva are retrieved from the files and processed, a results are transmitted immediately to the use online systems are interactive: the user a computer are in direct communication, and a can occur in real time.

The type of computer operation, the computer facility, the hardware configuration, software all are interrelated and each affe others. The entire system must be kept in bala harmony. For example, some input devices ar propriate for online or interactive operations storage devices are too slow for online ope Some programming languages are for batch op only. Some operating systems are suited for one processing only. The structure of the files fo processing may be inappropriate for online pro

In computer operations such factors as the s the computer, the size of the storage capacity, of the internal memory, the speed and capabi the peripheral units, the mode of computer op and the flexibility and sophistication of the s should be considered. These items must be ev in terms of cost and measured against the ol and requirements of the system applications.

ROLE OF THE COMPUTER

Computers were developed to do complex nu analyses and computations in the scienti engineering fields.[32] Their next application business and industry for routine processing involving little sophisticated computation bu repetitive operations. The third application wa area of symbol or language manipulation, in natural language, which is based on logical ope This area is still being developed, and its poten not been realized. Heuristic applications a possible, due to a computer's speed and ability its stored programs. This type of application the use of computers to play chess and checker write music and poetry. The final applicati

[30] Hayes and Becker, *Handbook of Data Processing for Libraries,* p. 651.
[31] Ibid., p. 664.
[32] Ibid., pp. 241-4.

control. Computers are used to control industrial processes, military systems, and even learning, as in computer-assisted instruction. More applications no doubt will be developed as the human imagination expands and technology advances.

The use of computers has become pervasive in society and commonplace in daily life. Paychecks, bank statements, creditcard bills, form letters, and bulk mail are computer-produced. Computer terminals are used in airports and hotels to make reservations, and grocery stores and department stores have cash register terminals. Names on tax rolls, voting lists, social security lists, census lists, and car registration lists are all in computer files. The electricity in homes is controlled by a computer system, and the telephone system is totally automated.

In all these cases the computer provides accuracy, consistency, reduction of duplicated efforts, speed, control, cost reductions, increased accountability, and more efficient use of human skills.

1. *Accuracy*. Once data are entered correctly, they remain correct and precise. The human errors of mistyping, misfiling, misadding, or transposing letters or numbers are eliminated.
2. *Consistency*. The same type of data will be handled the same way every time. The same logic is applied and the same decisions made every time.
3. *Reduction of duplicated effort*. The data in a computer can be recorded once in a master file and manipulated and sorted repeatedly as required.
4. *Speed*. The speed of the computer is unequalled. Even output is faster on a computer than most similar kinds of manual output would be.
5. *Cost reduction*. In most applications the use of computer is cost-effective when compared wit the cost of the same tasks performed manuall
6. *Control*. Because a computer system is tightl ordered by the software, control of the flow possible, the status of the system is alway determinable, and exception reporting is easil accomplished.
7. *Accountability*. Because of the way computer pro grams work, the computer can easily cour operations. Statistics are easily gathered, whic can give management valuable information fo decisionmaking.
8. *Efficient use of human skills*. Because data can b entered once and used over and over, as i producing address labels for repeated mailout human time can be put to more productive us Clerical staff can usually be reduced or rea signed to new tasks.

Yet computers are not a cure-all for the ills of th world. The computer is only as smart as its program mer. Output data are only as valid as the input data – the expression is "garbage in, garbage out." A operation can be paralyzed if equipment breaks or system goes down and backup is not available. System can be misapplied; software designed for one purpos is sometimes used for another purpose, with the resu of a mismatch of requirements and results. Ultimatel the computer is as effective as the human beings wh manage it.

CHAPTER TWO

ROLE OF COMPUTERS IN LIBRARIES

DIRECTIONS IN LIBRARY AUTOMATION

Like other segments of society, libraries have used computers in a number of ways. In general, though, full utilization of automation in libraries is yet to come. The question of how to apply computers to the functions of a library is answered differently by various writers. Usually, though, the traditional division of the library into public services, technical services, and administration is replaced by new arrangements of roles.

Cox, Dews, and Dolby classify library activities as *acquisition, processing,* and *dissemination.*[1] The library acquires materials, processes them to reveal as much as possible of the information they contain, and then makes the information available to those who need it, and even to some who never knew they needed it. The major effort involved is in handling the records of the materials rather than the materials themselves, and there are many different records for each item.[2] "The functioning of the library depends on the speedy and efficient handling of these records — their creation, consultation, amendment and updating,"[3] which creates an enormous data handling problem and one that is well-suited for computer application.

Swihart and Hefley recognize three main areas of library operations: library administration, library management, and library science.[4] Library administration encompasses acquisition, cataloging, and circulation. Library management involves the staffing, budget, and reporting aspects of acquisition, cataloging, and circulation, as well as the other areas of the library. Library science involves the materials, the catalog, the rules and schemes applied to the materials and catalog, and services to the users. Swihart and Hefley conclude that "automation is of most value and is applied primarily to [library administration]."

Hayes and Becker place computer applications in libraries into three categories: clerical functions, information storage and retrieval, and operations research.[5] Computers can be applied to the routine clerical functions of technical processing and circulation work to reduce the clerical burden and increase the library's ability to perform more work. Computers are applied to reference work in the field of information storage and retrieval. At the most complex level "the objective is to develop new methods for automatically aiding various intellectual processes, such as extracting meaning from text and correlating facts or inferring subject relationships from the complete content of articles and books." The areas of operations research and systems analysis require the use of "the computer as an aid in using the principles of scientific management in library administration" through provision of mathematical models and computer simulation.

Heiliger and Henderson see the library as not one system, but three.[6]

1. *Technical processes* are concerned directly with the acquisition of library materials and their cataloging, preparation for later use, and reference to the accumulated holdings.
2. *Control processes* are applied to the library's resources and to the handling of library materials and the processing of data about them, such as circulation, inventory, and work control information.

[2] Ibid., p. 11.

[3] Ibid., p. 15.

[4] Stanley J. Swihart and Beryl F. Hefley, *Computer Systems in the Library: A Handbook for Managers and Designers* (Los Angeles: Melville Publishing Co., 1973), pp. 11–15.

[5] Robert M. Hayes and Joseph Becker, *Handbook of Data Processing for Libraries,* 2d ed. (Los Angeles: Melville Publishing Co., 1974), pp. 5–6.

[6] Edward M. Heiliger and Paul B. Henderson, Jr., *Library Automation: Experience, Methodology, and Technology of the Library as an Information System* (New York: McGraw-Hill Book Co., 1971), pp. 7–13.

3. *Administrative processes* are concerned with the organizational structure of the library and its operations; the main emphasis is on providing quick and accurate access to basic records and statistics for sound decisionmaking.

They further suggest that the organization of the library reflect these systems: a professional services department, a data services department, and an administrative services department, as well as a liaison services department to reach the library's public more effectively. They propose that if computer applications would follow this new pattern of functions and services, automation could be used to better advantage.[7]

The essence of all these approaches is that a library should not use a computer simply to automate an existing manual system. The library must look beyond tradition and expand its thinking to take best advantage of automation.[8]

This leads to the question: Why do libraries automate? Allen Veaner wrote that there are three major practical reasons for automating library functions:[9]

1. To do something less expensively, more accurately, or more rapidly;
2. To do something that can no longer be done effectively in the manual systems because of increased complexity or overwhelming volume of operations;
3. To perform some function that cannot now be performed in the manual system — providing always that the administrator actually wants to perform the service, has the resources to pay for it, and is not endangering the performance of existing services for which there is an established demand.

The ultimate goal of all automation in the library should be, directly or indirectly, to improve the service supplied to the library user.

HISTORY OF COMPUTERS IN LIBRARIES

In 1962 a study was made of the potentia applying advanced data processing in a unive library. It was noted that[10]

> machine techniques have been applied successfully to a num data handling and service problems that appear similar to found in libraries, and it seems worthwhile to study the pot of routines that may suitably be applied to libraries.

The study concluded that[11]

> the speed of computers and the wide range of routines tha can handle offer possibilities for alleviating the pressu personnel shortages and turnover, of increased volumes of in ry and user activity, and of demand for more up-to-date re

In general this rationale explains why libr become involved in automation. Many libraries their first experiences with automation in the for the payroll, personnel, and budget control sys used by their parent organizations. Even today business applications are the only computer uses f in many libraries.

There was little library automation before the 1 Until then libraries used ADP (automated processing) equipment such as punch card rea sorters, and collators. This approach was used library by Ralph Shaw as early as 1948. A surv Federal libraries showed only five automated sys in operation in 1960 or before.[12] The survey, thr 1970, showed applications throughout the lib Table 8 lists these applications and the numbe libraries using computers to serve them.[13]

A 1971 survey of all types of libraries (acade public, school, special, State, and Federal) also sh applications throughout the library (Table 9).[14]

Markuson and her collaborators evaluated the surveys and concluded,[15]

> . . . most large-scale library automation activities occur environment that has relatively sophisticated computer ment and a fairly large and active computing center, and is oriented towards research activity.

These conditions occurred most often in acad libraries and in Federal technical libraries. In facilities, computers were already on hand and i

support of the research efforts — generally sophisti-ted applications in science and engineering. The earch environment fostered a parent group recep-e to the use of technology. The library thus had to ve sophisticated, demanding users. An additional ctor contributing to the favorable conditions was the fusion of funds for scientific research in the 1960s — ich more than was available for the humanities or blic service activities.

It should be pointed out that much of the early rary automation was in nontraditional areas, that is, her than acquisitions, cataloging, and circulation of oks and periodicals. In fact more than one-third of e operational systems in Federal libraries, as report- by Markuson, were classed as information retrieval, bliographic publications, selective dissemination of information, abstracting and indexing, and indexes to special collections. These systems dealt mainly with nonbook materials such as "research and developmen reports; journal articles; patents; trade literature including catalogs; laboratory notebooks; pictures and photographs; maps; reprints; archival items; and technical correspondence."[16] Many of these early efforts were performed in documentation centers or information centers, not libraries. The techniques used were those of documentation and indexing rather than cataloging. The two important standardized develop-ments in this area were (1) the ASTIA/DDC thesau-rus of descriptors and (2) the COSATI standard for document description.

Library automation underwent evolutionary re-search and development.[17] Standard business systems could not be applied wholesale to the library; specia software had to be created. Computer personnel had more experience in areas such as book ordering and fund control, but librarians were more interested in automating circulation, serials control, and catalog-ing.[18] A substantial learning period was required before much progress could occur. Standard input and output peripherals were often inadequate to handle the library's data. For example, they lacked upper and lower-case characters and diacritical marks Equipment had to be adapted and new technology developed in some cases, e.g., the American Library Association (ALA) print train.

In most of the earliest efforts each library worked independently to develop its systems. Redundant effor and incompatibility resulted.

Several developments helped advance library auto-mation efforts:[19] (1) The organization of such group as the Council on Library Resources, the Office o Science Information Service of the National Scienc Foundation, and the Committee on Scientific and Technical Information; (2) appropriations from majo Federal library legislation; (3) formation of such associations as the Information Science and Automa-tion Division of the American Society for Informatio Science; (4) development of the Library of Congres MARC II Communications Format for bibliographi data and the National Library of Medicine's MED

LARS. These developments focused attention on library automation, promoted new efforts, made existing efforts more visible, exposed more librarians to automation and educated them in its uses, and provided the methods and funds to allow more libraries to participate in automation.

The single development with the most impact on library automation is the MARC II format. The MARC format is a standard, and standardization is the key to future advances.

> Without a standardized format for the transmission of bibliographic data, we might not exactly be no place in library automation, but we would certainly all be riding off in different directions, dissipating our resources, and enjoying not the remotest possibility of interchanging bibliographic data or building networks.[20]

MARC allows full expression of the nature of the bibliographic entity being described and is structured so that full access is possible. The tag structure is designed for maximum flexibility and allows each library to manipulate bibliographic data as it chooses.

The availability of Library of Congress cataloging in MARC format through the distribution system has caused more libraries to accept Library of Congress cataloging and has reduced the amount of duplicated effort in libraries throughout the United States. The level of effort necessary to convert catalog data into machine-readable form has been reduced. The availability of library cataloging in MARC format has made it incumbent on most libraries to have their computer systems designed to handle the MARC format. This brings about more compatibility among computer systems, at least as a means of sharing data, and it allows greater cooperation among libraries.

Acquisitions has a standard — the International Standard Book Number (ISBN). The ISBN is not as well developed and widely implemented as MARC and, likewise, automation in the acquisitions area is not as well developed as in cataloging.

CURRENT EVOLVING TECHNOLOGY

The last 4 or 5 years have greatly advanced library automation.[21] Computer hardware now features greater speed and storage capacity. More sophisticated operating and management systems a cient use of the storage and CPU processing is widespread, and multipr mon. Advanced and economical tele techniques have been developed. Out can be equipped with a special print and lower-case characters and dia Computer-output microfilm (COM handle upper- and lower-case charac from more sources. Reliable, economi nals that can handle the idiosyncracie are available. Light-pen and optical- nition technologies have been refined these advances mean more efficient automated services.

could not afford their own systems now have access to the speed and efficiency of automated systems.

The early networks did not all succeed. Some lasted only by changing course along the way. The success of the Ohio College Library Center (OCLC) was the single most important factor that established the feasibility of networks. The reasons for its success can be debated.[23] Factors mentioned include the dynamic personality of Frederick Kilgour, the "father" of OCLC. The initial participation of top administrators of the organizations whose libraries were to be involved had an effect. Other reasons cited are that standard products and procedures were provided with few individual user choices and that outside funds and grants were infused at propitious times. OCLC monographic cataloging services are well established, and serials cataloging services are being implemented. Acquisitions and serials control services have been studied but are not yet underway.[24]

Online Files

Online large-file searching of major bibliographic files is available to almost all libraries. The development of this technology depended on several factors.[25] Important hardware developments include the online, time-sharing, third-generation computer, expanded direct access storage capacity, acoustical couplers for reliable direct-distance-dial telephone connections, and cable and microwave communications for transmitting data over great distances. Important software developments are in the area of natural language (nonnumerical) processing, as well as techniques. The availability of large machine-readable data bases originally built to support publication efforts was vital. Commercial, service bureau telecommunication systems such as TYMSHARE and Telenet made access available by telephone lines with local or nearby long-distance charges; the leasing of costly dedicated lines became unnecessary.

The factor drawing these elements together is the commercial intervention of such firms as Systems Development Corporation and Lockheed in multiple data bases available through one t and one hookup. The competition among commercial services has kept prices within r almost any library with a terminal.[26]

Packaged Software

There still is not much packaged software fo applications. The presence of any, however, i forward. Previously, each library had to bear own development costs. Transferring software l libraries has occurred, but not without pr Programs developed by manufacturers and available to other customers have been used, b without widespread success. An example is the 7 software developed by IBM for a circulation that is available as a Field Developed I (FDP).[27] In most cases, additional program required for the individual library applicatio ware developed for the Federal government, a in the public domain, is available at no c example, the NASA library package is availal COSMIC.[28] Commercial firms offer software es for lease or sale.[29] Blackwell North Ame library processing software that can be purch do Baker and Taylor and Systems Deve Corporation, with their acquisitions modules.

Commercial Services

Closely related to the packaged software a for libraries is the number of software commercial firms use to support the library they sell. Most of the major library jobbers a wholesalers have access to the MARC tapes computer-produced catalog card sets with o headings, spine labels, and circulation book reasonable prices, generally less than $1 per t smallest library thus can benefit from library tion. A set of cards ordered from the Li Congress currently costs $.45 for eight u (which may or may not be enough), all of wh

have file headings added, entailing the effort of typing and proofreading each. A little figuring shows the saving from the commercial sets. Additional library automated services from commercial vendors are the book and COM catalogs. Several vendors, such as Science Press, use MARC tapes for input to computer-produced catalogs. The input keying required is decreased, saving time and effort.

Computer-Output Microform

Computer-output microform (COM) is growing in importance in libraries.[30] COM is a cheaper, faster substitute for computer hardcopy output. COM catalogs are replacing card catalogs and book catalogs.[31] Elimination of binding and printing costs and of production turnaround time makes COM attractive and cost-effective compared to book catalogs, even considering the initial cost of purchasing viewers. The availability of COM with upper- and lower-case characters, bold and light faces, and alternate fonts such as italics has improved the quality of the image and made users more satisfied. COM reports are used in circulation systems and in acquisitions systems (for staff use where operations are batch or where permanent copy is needed for archival purposes).[32]

Telecommunications

The latest technology in library automation is telecommunications.[33] Mention has been made of this technology in terms of networks and online data base searching, for it is a major component of each. But telecommunications are developing to a point where further library applications are possible. Means of sending data efficiently and effectively are being developed all the time.[34] Computer data can be sent over voice-grade telephone lines. Commercial v are entering the field, and the resulting comp speeds advances in technology, improves servic lowers prices. Microwave transmission and con cations satellites, as well as cable television, are

What does this mean for libraries? For libraries, the telephone is the sole method of con cations. Some libraries within the framework o systems have Teletype terminals for interlibra transactions. For example, some States link ac libraries and State libraries via Teletype lines. studies of uses of its terminals indicate heavy us data base as a finding tool or union catal interlibrary loan searching. This connection libraries will grow stronger.[35] The sharing of re by facsimile transmission is inevitable[36] due to i ing production of information (the so-called in tion explosion) and decreasing funds for li Facsimile transmission equipment has been te libraries but its use has been limited by its costs a small number of libraries with the needed ment.[37]

FUTURE APPLICATIONS OF NETWORKS IN LIBRARIES

If someone walked up to you on the street and asked happening in library automation today?", and you were l a one-word answer, your response would probably l WORKS.[38]

The word "network" means different thi different people. By its most basic definition, a n is "an interconnected or interrelated group of where a node is "an end point of any bran network, or a junction common to two o branches of a network."[39] It can be discipli problem-oriented or serve a general funct

[39] *Introduction to Minicomputer Networks* (Maynard, Mass.: Digital Equipment Corporation, 1974), p. C-18.

computer network, which is the main interest of this book, is "an interconnection of assemblies of computer systems, terminals, and communications facilities."[40] It consists of links and nodes arranged in a given topology. At the simplest level a computer network may consist of a point-to-point connection of a host computer and a single communications input/output device. At the other end of the scale of complexity, a computer network can be made up of an interconnected group of computers, including processing systems (host, or main-site, computers and remote computers), communications control systems (e.g., data concentrators, message switchers, and front-end processors), and a variety of remote terminals and the transmission channels that connect the components.[41]

In general, networks can be said to provide a means for resource sharing that increases economy and convenience. Various kinds of resource sharing are possible.[42]

Device sharing. The ability to connect to and use the resources of a remotely located computing device as if it were local.

File sharing. The ability to read from, write to, or update files on a remotely located computing system as if it were local.

Program sharing. The ability to send a loadable program to a remotely located computing system to be loaded and executed by that system.

Program data sharing. The ability to open a data path between programs on an interactive basis, so that large tasks may be divided into smaller units for execution at different computer sites in the network.

Communications

The basis of any computer network is the communications link that allows interconnection between remote points. Networks have emerged as communications technology and computer technology have become integrated.[43] A computer network requires communications technology to function, and a data communications network uses computers to control its processes. The communications part of a connects, coordinates, and integrates the various nodes.

Each node can be made up of any configu processors, terminals, controllers, and softv nodes may vary considerably in speed, i languages, and other characteristics. These d are handled by the three basic types of func communications system: terminal functions, sion functions, and switching functions.[44]

> At each source terminal, the originating informatic converted to a form suitable for transmission to the re The signals must travel through whatever transmissio in the path of the information flow so that, when tl destination terminal, it is possible to recover the f information sent with some reasonable precision. . . . needed when information must be sent to any destinations and it is advantageous to allocate use of transmission path to users only when they need them.

The communications network must bring components into an efficient system. The arr or topology of the network can vary.[45] It can to-point, multipoint, centralized (or "star"), cal (or "tree"), loop (or "ring"), distrib "multistar"), or fully distributed. For a libra these topologies is possible.

The main impact on libraries is due to the of commercial communication systems. I having to own point-to-point private lines, can use a public-switched telephone networ Data-Phone 50 or can lease private lines telephone company or a specialized commo (WATS, TELPAK, TELEX, TWX, and M real value is a commercial service like TYM TYMNET which provides a network-only customers who wish to attach their own con the network and offer service to their group.[47] Users can dial one of 80 metropolita the United States, Canada, and Europe incurring charges for long-distance calls.[48] tional Library of Medicine has attache computers to TYMNET.[49] SDC and Lockl

bases are accessible through TYMNET.[50] The Federal library-OCLC project also has used TYMNET.

Computers

If communications is the "how" of the network, the computer is the "what." A computer network can provide device sharing, file sharing, and program sharing. The ARPA network of the Department of Defense's Advanced Research Projects Agency was planned and developed as an experimental computer network to demonstrate the feasibility of interconnecting and sharing hardware and software systems.[51] When additional resources are required (e.g., additional storage or a faster printer), the process is shifted to another available node in the network.

A time-sharing computer network such as the General Electric Information Services Network[52] allows many remote users to have access to a computer facility which simultaneously processes many completely different problems and allows each user to act as if he or she had sole control.[53] A library can use a time-sharing service to access a computer if it hasn't one of its own, assuming of course that the necessary software is offered by the service bureau.

Information

Infinite variety is possible in the scope and application of networks. Information networks are used by airlines to search data bases of flight schedules and reservations. There is a network of Census Bureau data. There is also a network of stock market information, including Dow Jones averages, stock prices, statistics on the most active stocks, and historical statistical data on stocks.[54] The National Library of Medicine's MEDLAR network is made up of journal and report citations, not the materials themselves.

The major determining factor in the topology of such a network is the type of participation of the nodes.[55] They can be providers of resources exclusively, users of resources exclusively, or combinations of the two. A library can participate in any of the

bers.... [They must] come to grips with the following new systems concepts: the new generation of mini- and midicomputer hardware; distributive data processing wherein those functions better performed locally are done at the user's location; and development of replicable multipurpose software/hardware packages available for lease or purchase.

ROBLEMS IN CURRENT LIBRARY PPLICATIONS

Literature reviews indicate that library automation - application of the computer to routine operations nd services in a library — is firmly established in the brary world.[62] The decision for a library is not so uch whether to automate, but rather when and how. lper suggests that this continued application of omputers in libraries is an evolutionary process that ictates continual review of past efforts to determine e characteristics that made them succeed or fail.[63] his information then can be applied in future pplications.[64]

Most of the problems in the past have been in three ain areas: poor or inadequate systems design; poor ommunications and misunderstandings between li- rarians and data processing professionals; and poor inadequate data processing assignment, software, nd access to personnel and equipment.

oor Systems Design

Poor systems design and resulting project failure is ot unique to library automation.[65] Libraries do have propensity for systems problems because librarians in e past often have used informal and unscientific lanning and management techniques. Data processing systems require a much higher degree of standardization, centralization, and uniformity than manual ystems.[66] Cox, Dews, and Dolby spoke of a great ause of misunderstanding between the library and the omputer center being what is *not* said about the details f various library operations.[67] The librarian assumes at the implicit details of a library procedure are obvious. This problem can be eliminated if a proper, thorough systems design is performed, and a complete systems document is prepared. The following pitfalls have occurred from improper planning for library automation.[68]

- Setting improper goals
- Making an incomplete analysis
- Selecting wrong applications
- Allowing too little time to complete all phases of the system
- Underrating the cost of the installation or system
- Not keeping employees informed

Related to poor systems design is the mistake of automating manual procedures instead of automating with a view to what the computer can do and to what expanded services and applications are possible.[69]

Poor Librarian/Computer Personnel Interface

"It is abundantly clear that elegant technology cannot be exploited and complex systems cannot be sustained by hostile, fearful, or untrained personnel."[70]

Both library and computer center personnel have been guilty. Computer firms have not recognized the peculiarities of library operations and have to tried to install "another address list program" or "another parts inventory system." Librarians feel ill-prepared to cope with the mechanical, the mathematical, and even the logical aspects of library automation.[71] They often avoid automation in order to avoid feeling uncomfortable or inferior. They often defer too much to technical people, which leads to poorly conceived systems. As Markuson says, a librarian cannot say to someone, "Come automate my library."[72] A team approach must be used with all team members doing their homework. For example, the different definitions and meanings of such terms as "file," "list," and "record" in library and computer jargons must be recognized and dealt with.

Poor Support

Libraries often have suffered from a mismatch between their needs and software capabilities, hardware functions, and access time. At one level, the entire industry could not meet the needs. OCLC had to develop and engineer an extended-character-set CRT terminal,[73] and ALA had to sponsor development of a print train with the proper diacritical marks for printing library catalog cards. Most standard software packages cannot handle library filing. Most service bureaus do not provide programs for library operations.

At a local level, the data processing facility used by a library's parent organization often did not have the proper hardware or software to support the library's requirements. Libraries often found their access to the equipment limited and their priority low. Agency data processing staff had little time and little expertise for library systems. Library systems have suffered when hardware configurations have been changed without considering library needs. These problems have affected all types of libraries: academic, research, Federal, and public — all libraries that must rely on outside data processing support. Yet few libraries can afford their own computer facility.

Other Problems

In existing automated library systems, several problems have arisen that must be resolved before further growth of library automation will be possible. One need is for a technically and economically feasible means to convert cataloging records to machine-readable form and to make widespread access to those converted records possible. Independent efforts are too slow and costly, but full use of online bibliographic files as union catalogs is impossible without conversion.

Another need is for a means to transfer data and systems between libraries and between networks. This problem arises from lack of standardization, which is a result of the typical librarian's mind set and approach to management. It can be predicted safely that technology to accomplish such transfer will arrive before the human mind is psychologically prepared to use it.

FEDERAL LIBRARY AUTOMATION APPLICATIONS

Automation in Federal libraries is at many diff stages of development, from nonexistent to a garde. The purpose of Federal libraries varies providing leisure reading to supporting the scholarly research. Size of allocation, size of staff size of budget vary from library to library, administrative structures vary from one single mous library to a branch structure of more thar small units. The problems of automation in Federal libraries are the same as those in libraries with the addition of a few peculiar cir stances. Federal libraries have strict budget staffing requirements, for example, and con procurement and contracting procedures. It is environment this book addresses.

HOW THE MINICOMPUTER COULD HELP

What is a minicomputer? How is it different fr regular computer? How can minicomputers help a library's automation requirements?[74] These are questions, but they are not easily answered.

What is a minicomputer? It is a computer machine that manipulates symbols in accordance given rules in a predetermined and self-dir manner. It is made up of a central processing u memory, and input and output devices. It op under the control of its programs. What then ma computer a minicomputer? The distinction is o size — physical size, size of memory, size of word of storage capacity, size of repertoire, size of price problem is one of drawing the boundary to distin between sizes. One must ask, "Compared to w Definitions of minicomputers vary according t range or boundaries set.

Auerbach (1974):[75]

> A minicomputer is a small, stored-program digital comput can be programmed in an assembly or higher-level langua which has the following attributes:
>
> 1. Sells for less than $25,000 for a minimum, stanc configuration comprised of a central processing unit, m input/output equipment, and system software.
>
> 2. Contains a memory of at least 4000 eight-bit words.

[73] Long, "Computer Technology," p. 213.

[74] Grosch explained the rationale for selecting a minicomputer over a large-scale computer to develop an integrated library automation system. See: Au Grosch, "Mini-Computer Systems for Library Management Applications; A New Approach to Bibliographic Processing," in *Computers in Information Data Cen* Joe Ann Clifton and Duane Helgeson (Montvale, N.J.: AFIPS Press, 1973), pp. 25–33.

[75] *Auerbach on Minicomputers* (New York: Petrocelli Books, 1974), pp. 2–3.

Performs normal computer functions (inputs, transfers, stores, rocesses, and outputs data) under stored-program control.

Is usable in a broad range of applications.

Demitriades (1974):[76]

/hat is a minicomputer? In general terms, it is a physically small, latively inexpensive, highly reliable computer that has a stored rogram capability and requires little or no environmental ontrol. However, the range in cost and capabilities is very road.... There is, however, a "most common package" covering pproximately 80 percent of the minicomputers in use today. Its asic unit price range is from $2000 to $10,000; a workable system ith memory and peripherals will cost about $20,000. The size of television set, it will store about 4000 words of 16-bit memory nd process at about 5 millionths of a second. Its modular design lows for easy add-on.

ne definitions reflect the varied uses of the minis. Snyder (1975):[77]

n acceptable definition of the minicomputer is elusive.... Most uoted of the suggested specifics are: a core size of 4,000 to 8,000 ords, and a selling price somewhere in the vicinity of $5,000. . they're usually referring to a central processor, with 4 to 8K of ore memory and possibly a teletype.... [However] it's not a unctional machine. When you talk about a true mini business stem, you have to include a general purpose computer and the ormal input and output devices... and considerably more core an the 4 to 8K....[The definition must be qualified to] any omputer system that is capable of handling typical business pplications — billing, payroll, inventory control, etc. — and that an be purchased for a total cost of less than $100,000 or rented for ss than $2,000 a month.

Pearson (1975):[78]

computer that, with its associated software and peripheral quipment, is priced low enough (from $65,000 or so) to be fordable by a medium-sized library, and with sufficient capabili- to support most library data processing needs.

STORY AND DEVELOPMENT

The minicomputer was developed in the 1960s as an growth of third-generation computers.[79] The first nicomputers were for special applications. That is, h was designed for one purpose only. The early plications were in industrial control; minicomputers re used as low-cost controllers of discrete and ntinuous processes in automated laboratory or ustrial equipment. Almost all of the minis were rchased by manufacturers to be incorporated in ir products.

A number of technological advances made minicomputers possible. The main advance was the development of integrated circuits that were extremely small and could be mass-produced economically. The electronics field advanced from mechanical switches and relays to vacuum tubes to transistors and solid-state circuitry, and at each step computers became smaller and faster.[80] The discrete components of transistors, resistors, and capacitors were replaced by an integrated circuit called a small-scale integration (SSI) chip, and then by the large-scale integration (LSI) chip. (Chips are extremely small. They are usually about 3/8 by 3/4 inch and about 1/8 inch thick, and each chip can represent thousands of transistors.)

This miniaturization did not lessen the power of minicomputers, which were more powerful than most second-generation large computers. The industrial applications proved minis to be powerful, fast, low in cost, and very reliable.[81] The success of the mini as a controller and monitor led to other uses. Eventually minicomputers broke free of the special application mold, and general-purpose minicomputers were developed.

CHARACTERISTICS

Minicomputers are noted for their flexibility. In fact, Vosatka suggested that "multicomputer" would be a more appropriate name.[82] The other major characteristic of minicomputers is low cost. In 1974, Auerbach reviewed the characteristics of minicomputers that result in their lower cost compared to that of large computers.[83]

1. All have simple, i.e., limited, instruction sets, both in absolute number and the power of instructions provided.
2. All have small memories....
3. Word length is short, which permits design economies in the central processor electronics.
4. All have simple input/output (I/O) control capabilities.
5. Elimination of such features as real-time clocks and parity checking from the basic standard as opposed to optional system is cost inhibitive.

Paul B. Demitriades, "Mini Update," *Journal of Systems Management* 25 (December 1974):

James E. Snyder, "Small Computers for Small Business," *Journal of Systems Management* 26 (August 1975): 26, 28.

Karl M. Pearson, Jr., "Minicomputers in the Library," in *Annual Review of Information Science and Technology*, vol. 10, eds. Carlos A. Cuadra and Ann W. Luke

6. Slow and relatively unsophisticated peripheral devices are used.
7. Minimal system engineering support is needed.
8. A limited amount of comprehensive system software is supplied free with a system.

These characteristics are disappearing in some machines due to advances that make greater computing power possible for the same or less money. For example, minis are available with more main memory, longer word lengths, larger instruction sets, simpler and more efficient I/O systems, and more system software provided. The distinction between large-scale computers and minicomputers is blurring; system prices are increasing. The smaller large computers and larger minis overlap, and such names as "megamini" and "super-mini" are used by some to describe these machines. The IBM System 3 and the Burroughs 1700 are two common systems in this borderline category.

In general, the philosophy of minicomputers is different from that of large-scale computers. The minicomputer environment is one of closeness and contact. There is a "minicomputer attitude," which is described thus.[84]

> People with minis have time to get to know the computer. People with minis get to know their application on the computer. People with minis become intimate with the computer.

With the use of minicomputers, there is a shift from centralization to distributed computing, from central control to local control. A standalone computer can be dedicated to a single use and placed at the point of use. Communications delays are eliminated and data entry problems minimized. Mini systems are modular, and thus more easily configured to meet specific requirements than are large computers. The technological advances come faster in the minis because the development cycle is abbreviated and adjustments to new technology are easier. This all adds up to an open, responsive atmosphere that makes automation less forboding and more approachable.

DEFINITIONS

In choosing a definition for the word "minicomputer," it seems wise to be inclusive rather than exclusive. The dollar value is important but cannot be definitive due to inflation and Government procurement procedures. The entire system, hardware and softw be considered in the definition, and the syster functional. The hardware should not requi environmental conditions. That is, it should at the point of contact, but physical size or d are not necessary to the definition. That l following definition: *A minicomputer is a physi relatively inexpensive, general-purpose computer that in a regular environment with as much peripheral support as is necessary to meet the requireme application.*

Even though minicomputers are only a l than a decade old, they too have gone development phases or generations (Figure 1 "micro" systems are smaller, cheaper, and les cated than minicomputers.

Microcomputers, microprocessors, micro these terms often are used interchangeably. with all the CPU functions is called a micro Frequently it is used with other chips that h I/O and memory functions. A microcomp minicomputer built around a microprocesso computers are often used as controllers devices, and these often are called microc

BASIC USES AND APPLICATIO

Minicomputers have been used in five mai application.[87]

1. Industrial process control
2. Peripheral control
3. Data acquisition
4. Communications
5. Computation.

Industrial Process Control

Minicomputers first were used in the indus The minis control processes and mach operate equipment; and test systems, subsys components for quality control or monit maintenance in the field. A mathematical m process is used. Minicomputers often are ma of a system assembly or other machine by tl equipment manufacturer. Minis are used traditional electromechanical control systen they can handle more complex systems ai

adapted to changes in materials or processors by merely changing their software.

Peripheral Control

Minicomputers are used instead of hard-wired controllers to control peripheral devices such as terminals, data entry systems, or computer input/output devices. The mini can service interrupts; control input/output; and perform sequencing, data transfers, buffering, editing, and formating so that the main CPU's control unit need not be used for these purposes. This allows better CPU efficiency.

Data Acquisitions

Minicomputers are used to acquire data in industrial and military applications, research and development organizations, hospitals, and laboratories. They provide a real-time interface with sensors, counters, test or measuring devices, satellites, or other data-gathering instruments. They accept data from multiple sources at high rates, and then store, log, edit, format, and/or preprocess the data.

Communications

Communications networks use minicomputer munications control processing in three different as front-end processors, as data concentrators, a message-switching units.

A front-end processor is located close to the computer and is placed in the data flow betwee host and a number of remote data terminals (or computers). The front-end processor performs communication control functions such as line co error checking, code conversion, automatic answ polling and addressing, and character-to-m assembly and disassembly.[88] The host processo mainframe CPU) thus makes more efficient processing time and memory requirements. A computer used as a front-end processor is more fl and economical than a hardwired device and can to maintain network operations if the host com should go down.

A data concentrator is remote from the computer and serves to coordinate and op transmission of data. It accepts messages from terminals via low-speed lines and transmits them

[88] *Introduction to Minicomputer Networks,* p. 3-3.

host via a single high-speed line. This reduces line costs by more efficient use of the lines. A minicomputer functioning as a data concentrator can be programmed to perform the data communications control functions as a front-end processor; to accommodate interfaces to special terminals; to buffer input/output differences; and to accommodate changes in data rates, formats, codes, communication procedures, and number of terminal devices.[89]

A message-switching unit is an intermediate point in the data flow. An entire message is transmitted to a message-switching unit, where it is stored for a period of time.[90] It is then transmitted to its destination, which is designated by an address in a header field in each message. The unit accepts messages from multiple sources, logs the messages, routes them to multiple output lines, and verifies their transmission. A minicomputer as a message switcher does more than route traffic. It lets a terminal send a single message with multiple addresses, eliminating retransmissions for each address, and it temporarily stores data on disks or magnetic tape, converts codes, edits, logs, and polls and addresses terminals. It saves line costs by allowing messages to be transmitted at top speed and one line to be shared by several terminals.

Computation

Minicomputers are used for computations or problem solving. This is a standalone application in which the mini is used as a large-scale computer — it performs input, manipulation, and output operations while independent of any other computer. It is used in applications that could be served by a large-scale computer but are more efficiently served by the mini. The mode can be batch or online, dedicated or timesharing. Minicomputers have been applied thus in business, education, engineering, and research.

MINICOMPUTERS IN LIBRARIES

Minicomputers have many potential uses in a library. Except for data acquisition, any of the five main areas of application could be found in the library.

Many libraries already have minicomputers some unknowingly. A Xerox 9000 has a minicompu as its control unit. Other common library equipm with microprocessors include magnetic-card typew ers, desk calculators, and microfilm readers. So libraries that are part of large-scale computer syste have a microprocessor-controlled peripheral, i.e., minal, or an intelligent terminal that performs fro end editing and error control.

Pearson highlighted the early applications of mi computers in libraries.[91] Minis were first used as d collection units in batch circulation systems. In application the information for each transaction recorded by the mini and stored with other trans tions to be transmitted in a group to the host compu for batch processing of the files and production of reports. Minis next were used as remote processors well as being used as locally available small files (e bad borrowers files and hold or reserve book files). major file updates and reports still are handled by host computer in a batch mode. Ultimately minis w applied to circulation as standalone units to han transactions in an online environment.

Minicomputers have been applied in similar way support acquisitions, technical processing, catalogi film booking, and selective dissemination of infor tion.

Minis have also been used in larger system confi rations as terminals, communication control ur and/or remote computers. The Stanford Univer BALLOTS system uses a minicomputer as a com nications controller and as a programmable termi connected to an IBM 360 mainframe or host comp er.[92] The University of Chicago Library data mana ment system uses a minicomputer as a remote conc trator (communications controller) to handle network's 50 terminals.[93] Information Dynamics C poration's BIBNET system used a dispersed comp

[89] Ibid., pp. 3-5—3-7.

ing approach, with minicomputers functioning as remote processors.[94]

The last major type of library application is the minicomputer "turnkey" system.[95] This commercial, on-the-shelf package is complete and ready to use on installation. It includes minicomputers, peripherals, and software necessary to perform specific library functions on a production basis. The Computer Library Services, Inc.'s (CLSI) LIB 100 circulation system has been installed in more than 50 libraries.

SUMMARY

Minicomputers, although not a panacea, can and do have a place in libraries. Their role in library automation will increase. The attributes of minicomputer systems contribute to the library automation environment in a number of ways.

- *Local Control.* Because minicomputers are small and require no special environmental controls, they can be installed in the point of use (that is, the normal library environment). The library staff thus controls the operation of the system, reducing problems of access, long queues, scheduling time, and low priorities.
- *The Mini Attitude.* Because the mini is housed in the library, it is more approachable for the library staff. There is more hands-on use of the system, which encourages the staff to understand and accept the system.
- *Smaller/Simpler System.* As a rule, the minicomputer is a smaller, simpler "machine." It lends itself to applications and environments that previously were considered too small to justify automation.
- *Modular System Development.* Because a mini l itself to small, discrete applications, a library build a total system on a modular block-by-l basis. Individual systems can be integrated i whole library system.
- *Custom Configurations.* Minicomputer hardware the minicomputer industry are such that a sy configuration can be tailored to meet indivi system requirements. There are few one-ve shops in a minicomputer environment. Hy mixed-breed systems are common.
- *Adaptability.* With large-computer systems often so costly and time-consuming to ch vendors or upgrade equipment or software systems remain stagnant or become out of da default. This is not true of minicomputer sys Changes can be handled much more easily.
- *Low Cost.* The main characteristic of minicor ters, their low cost, allows more librari automate. Although they are not cheap, r computer systems are relatively inexpensive pared with large-scale computers, and they l about a greater dollar return and cost/be ratio.

No library can afford to ignore the possibili applying a minicomputer to its operations. This is for libraries with no experience with automati well as for those with functioning, full-scale auton systems, for minicomputers do not have to con with large-scale computer or time-sharing sys They can supplement or complement such sy instead. Again, their keyword is flexibility.

CHAPTER 3

MINICOMPUTERS—DESCRIPTIONS

In general terms, minicomputers are functionally and operationally the same as large-scale computers. There are differences, though, and this chapter describes these divergences from the general description of computers in Chapter One. The differences stem from the facts that (1) minis are smaller and therefore simpler, (2) they are "younger" and have not evolved as far as large-scale computers, and (3) they are usually designed for single applications, whereas large-scale computers are general-purpose systems.

Minicomputers are approachable. Users can see and touch them. For this reason they need not be viewed as "black boxes." Many people become interested in minicomputer systems as a hobby, much as stereo buffs get into audio components and systems. Many systems are put together as hybrids with equipment from various manufacturers. While this can be a strength, allowing the user to have a system that truly meets his needs, it can make selection of a system technically complicated.

This chapter alone will not prepare librarians to assemble their own systems. References to additional sources are given for users who would like to take this approach.[1] The more general goal is to prepare librarians to deal with system requirements, specifications, and selection criteria as members of teams that include data processing experts. Librarians should seek the advice of experts but should not be intimidated into deferring too much to them.

A block diagram of a minicomputer configuration has the same basic components as that of a large-scale computer configuration (Figure 17). Minicomputer software also is basically the same as that of large-sc computers. It includes library subroutines, assembl compilers, file management programs, and operat systems as well as the application programs.

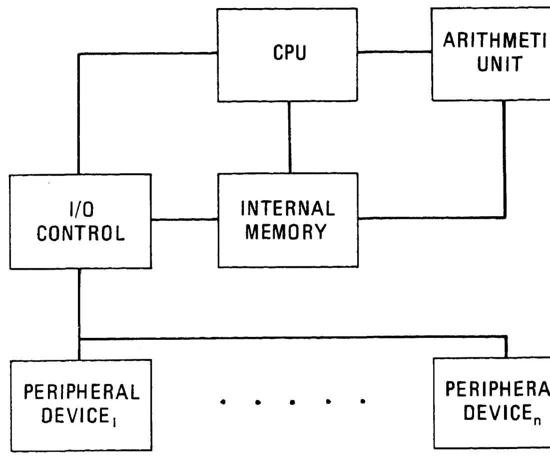

FIGURE 17. Block diagram of a minicomputer configuration

The specific components and configuration determined by the application. For data commun tions network applications the main distinction tween configurations is in the physical location of equipment. For example, a minicomputer conne to a host to serve the communications control proc ing for a number of nodes or terminals can h basically the same components whether it is a fr end processor or a remote concentrator (Figure

[1] Cay Weitzman has written a basic text on minicomputers. His Preface statement defines the scope which is of the same philosophy as this book: "To i success, the user must not only take the time to determine what the system must accomplish *for him* but also have a fundamental working knowledge of the quali and quantitative design approaches to minicomputer systems evaluation, selection and interfacing, and hardware, software, and firmware integration. Quick, p supported decisions coupled with lack of knowledge of the various details of minicomputer systems analysis and design will in all probability result in an unsatisfa selection or solution to the problem. My purpose is, therefore, to give the system designer and/or user an overview of latest minicomputer hardware and sof technology, tools, procedures, and approaches used in evaluating and designing minicomputer systems as well as guidelines as to how to implement,maintai support these systems" (pp. xi–xii); *Minicomputer Systems; Structure, Implementation, and Application* (EnglewoodCliffs, N.J.: Prentice-Hall, 1974). Eckhouse's boo computer organization and assembly language programming. It uses the PDP–11 asthe real machine the examples are based on; Richard H. Eckhous *Minicomputer Systems; Organization and Programming (PDP–11)* (EnglewoodCliffs, N.J.: Prentice-Hall, 1975). Barna and Porat have written anintroducti microcomputers; Arpad Barna and Dan I. Porat, *Introduction to Microcomputers and Microprocessors* (New York: John Wiley& Sons, 1976). The *Microcomputer Dictiona Guide* is a good reference book for micros and minis; Charles J. Sippl and David A. Kidd (Champaign, Ill.: Matrix Publishers, 1975).

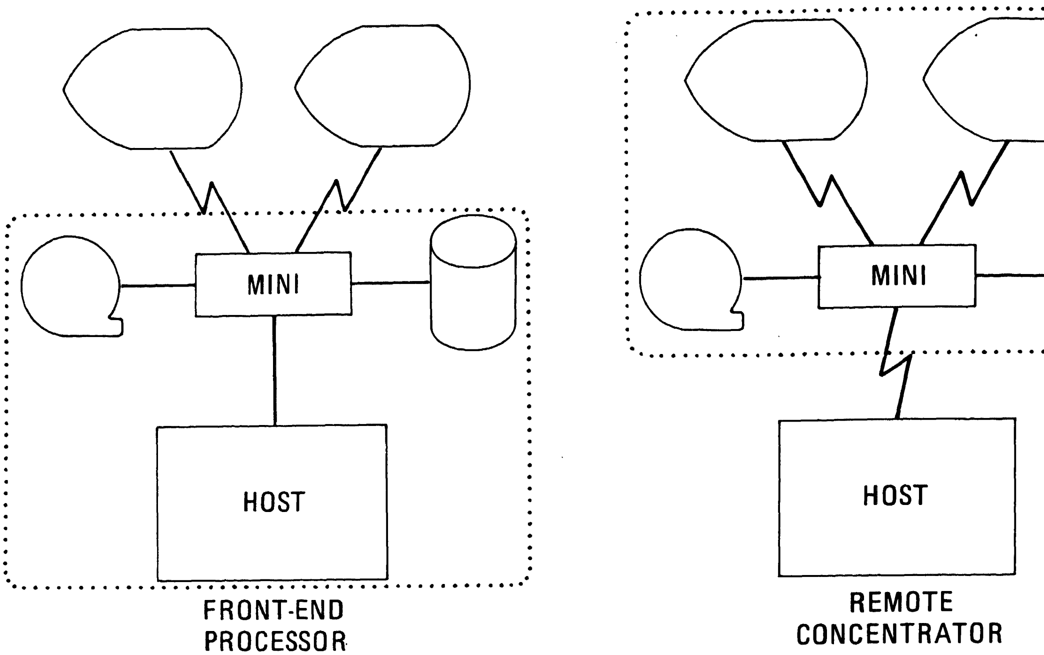

FIGURE 18. Configuration of a front-end processor and a remote concentrator

Front-end minis are located at the same site as the host computer; remote concentrator minis are located at the remote site and are connected to the host by telecommunications lines.[2]

As far as library applications are concerned, the configuration varies according to input requirements, output needs, storage demands, etc. The specific library applications and typical configurations will be reviewed in later sections. In this section the general elements of the hardware and the capabilities of the software will be described, and their roles explained.

HARDWARE

MAINFRAME

CPU

The minicomputer mainframe (CPU plus main memory) determines the power of the system. The main characteristics considered in describing and evaluating the structure, or architecture, of the CPU include the following.[3]

- Instruction set
- Addressing capabilities
- Instruction execution speed
- Number, size, and arrangement of and/or index registers
- Number of interrupts and method them
- Optional features

More technical definitions of each of t can be found in a number of texts. The one of these elements can be overcome b the system with additional hardware o design; none can be taken as definitive or

Instruction Set

The instruction set is composed of the language or commands that represent tasks performed.[4] They include logic st as AND and OR; load/store statem MOVE DATA and LOAD ACCU arithmetic statements such as ADD, TWO'S COMPLEMENT, and SHIF statements such as COMPARE, SKIP UNCONDITIONAL JUMP, and TES

[2] James F. Corey, "Configurations and Software: A Tutorial," in *Applications of Minicomputers to Library and Related Problems,* ed. F. WilfridLancast at the 1974 Clinic on Library Applications of Data Processing, 28 April to 1 May 1974 (Urbana-Champaign, Ill.: University of Illinois, Gradua Science, 1974), p. 17.

[3] *Auerbach on Minicomputers* (New York: Petrocelli Books, 1974), p. 17.

F SET OR RESET. The simpler CPUs have very few structions in their sets. In terms of the application, e number of instructions provided is less important an the kind of instructions. In any case a programer can write routines to accomplish these tasks. It mply takes more development time and makes the rogram larger and slower.[5]

ddressing Capabilities

The addressing capabilities of the CPU are deterined by the length of the instruction word, the rocessor logic, and the memory size.[6] The word ngth is the amount of data that can be stored in one emory location; it ranges from 8 to 24 bits. The eans of identifying the data in each memory location nd making it available for use is called the addressing cheme. The Sams book presents a simple explanation f addressing:[7]

> Memory cells are very similar to post-office boxes. Post-office boxes are numbered in sequence on the outside of the box. We will number our memory cells from 0 to 63, a total of 64 memory cells, each one holding 16 bits of data. When we talk about the contents of memory cell 17, we may visualize a post-office clerk going over to box number 17 and withdrawing a post card with a 16-bit value printed on it. . . .The 64 memory cells contain either data values or instructions (or nothing meaningful if a cell is not used). The data values might be used by add or subtract instructions, or for comparisons. Cells might also be set aside, or reserved, for the results of operations. If there were no pieces of data or reserved cells in memory, there would be room for 64 instructions. If there were instructions in locations 0 through 23, there obviously could be no data in these locations at the same time.

he instruction word becomes the key. It must, as xplained in Chapter One, specify (1) the operation to e performed and (2) where in the memory is the data o be operated on, where it is to be located after being perated on, and where in the memory is the next nstruction. That means an instruction word of 16 bits divided into a two-part format.[8] The first 4 to 6 bits re assigned as the operation code, and the remaining 0 to 12 bits are for addressing.

Most minicomputers use one-address instructions, hich means that one instruction can address only one emory location.[9] Going back to the post office nalogy, each memory location has a unique number s its address. With 12 bits representing a base-two numbering scheme, only 4096 unique numbers can be specified, or, only 4096 memory locations can be addressed. When memory sizes are greater than 4096 locations, means of addressing memory other than direct addressing must be used. Different manufacturers use different methods. The most common are direct or absolute, immediate absolute, paged, relative, indirect, and indexed addressing. "For these techniques, part of the address field (for example, 3 bits) selects the addressing technique or mode and the rest of the field (9 bits) operates as an address, an address displacement, or an operand."[10] Some techniques use special registers, counters, or stacks to extend the number of locations that can be addressed. The technique used affects the memory size that can be used, the speed of processing (number of cycles required to support an operation), and the difficulty of programming the system.

Instruction Execution Speed

The instruction execution speed depends on memory cycle time as well as on the CPU's internal logic (the way the cycles are used to perform the operations). As a basis for comparing CPUs, the speed is often measured in terms of performing a standard operation, such as the add time as well as the cycle time. Cycle time can be defined as "the time to read (and restore) a single word in memory"[11] or the "minimum time interval, in microseconds, between two successive accesses to a particular storage location."[12] Add time is variously defined, but in general it represents the time required to perform an add operation ($C=A+B$), including the time used in accessing both operands from memory and storing the results in working storage.[13] Even these times are not always directly comparable, due to the way the manufacturer performed the test. Other factors that affect speed in complicated systems are the load on the system and the use of such techniques as time-slicing.

Register Configuration

The number, size, and arrangement of accumulators and/or index registers really determine the architecture of the CPU. There are two basic types of CPUs,

[13] Ibid., p. 98 and Dennis Hollingworth, *Minicomputers: A Review of Current Technology, Systems, and Applications* (Santa Monica, Calif.: Rand Corporation, 1973), p. 13.

special-register processors and general-register processors.[14] In special-register processors "one of the operands specified by the instruction resides in a main memory location and the other resides in either the accumulator or some other special-purpose register." For special functions there are special registers, such as accumulators; extend registers, which may be logically linked to accumulators; index registers, which are used in addressing; and others for program linkage, etc.

General-register processors do not define the functions of the registers but allow them to be used as accumulators, stack pointers, or index registers depending on program requirements. This gives greater flexibility. Most processors also have nonprogrammable registers that operate as buffers to hold a word temporarily for the processor hardware (e.g., program counters).[15] A variation has been introduced with a mechanism called a stack.[16] The stack is an ordered collection of memory locations or hardware registers with a top or first element, a second element, and so forth, in which only the first element can be accessed. A "pushing" operation loads the elements one at a time in sequence, and a "popping operation" takes the top element off and moves every element up one position. The number and arrangement of the registers affect programming ease and flexibility as well as execution efficiency.[17]

Interrupts

The number of interrupts and methods of handling them allow the processor to interact with the entire computer system. "An interrupt is a signal that causes the processor to suspend execution of instructions in the current program and to branch to a set of instructions that deal with the interrupt condition. When the interrupt has been taken care of, the processor continues to execute the suspended program."[18]

There are two types of interrupts: internal and external. Internal interrupts, or traps, deal mainly with abnormal, error, or occasional conditions (e.g., illegal address, power failure, memory parity error, and overflow from fixed-point arithmetic operation). External interrupts deal with devices external to the processor, such as the peripheral devices. Because the processor speed is very great and the peripheral devices are by comparison very slow, the processor p other functions until the peripheral sends an i signal to say the input or a character is rea transferred. Once the transfer is complet processor returns to the program it was executi the interrupt occurred. Generally the extern rupt expresses the cause or condition that trigg interrupt, such as error, malfunction, charact for transfer, operation finished, end of block, complexity of the interrupt system, called the v mechanism, depends on the number of li number and nature of the devices, and any structure used.[19]

Optional Features

Optional features available from many man ers may be appropriate for specific applicati types of features offered include power f memory protection, memory parity, floati arithmetic, decimal arithmetic, and byte m tion.[20]

Main Memory

The main memory of a minicomputer is d by its word size and capacity. The word leng amount of data that can be stored in one location, and the capacity is the total nu memory locations or words available. Commo ity sizes are 4K, 8K, 16K, 32K, 64K, 128K, a where K is nominally 1000, but in actual meas K represents 1024. The size can be thought of of word capacity or character capacity, and can be made based on the best, most combination (e.g., 8K 8-bit words or 4K 16-bi Table 10 shows some representative combinati

TABLE 10—Common Sizes of Main Memory

Word Length	Word Capacity	Character C
8 bits	4 K	32,768
8 bits	8 K	65,536
8 bits	16 K	131,072
16 bits	4 K	65,536
16 bits	8 K	131,072
16 bits	16 K	262,144
16 bits	32 K	524,288

The available types of memory are ferrous-core and niconductor.[21] Ferrous-core memory is the kind scribed in Chapter One. It is nonvolatile, which eans that if power is lost the contents remain stable. ne average speed of core memory in a minicomputer nges from 0.8 to 1.5 microseconds. A semiconductor emory is a solid-state, integrated circuit module ually called a chip. The density of the chip is pressed as LSI (large-scale integration). The materi- of which the chip is made constitutes an additional eans of classification (e.g., bipolar semiconductor emory and metal oxide semiconductor, or MOS, emory). Semiconductor memory is faster than core IOS averages 0.45 microseconds and bipolar averag- 0.3 microseconds), but it is volatile — the contents of emory are lost in the event of a power failure. Most emory has both read and write capability. A special nd of chip is used in some equipment that has read- ly capability.

The ROM (read-only memory) is a memory ntaining permanently available, frequently used ograms and/or data. It is designed and sequenced as is manufactured. It cannot be changed and is latively slow. A ROM is nonvolatile in that the ntents will remain even if the power source is terrupted. A new modification now available is a ROM chip, or a programmable ROM. The pro- ammer can decide on the subroutines, which are tered electronically at the beginning but are not sily changed and are not under program control as her memory is. ROMs and PROMs have figured avily in miniature systems, controllers, and micro- mputers.

nput/Output Control

Input/output control transfers information between e processor of memory and I/O devices in response signals from the control unit and the external ripheral devices.[22] An I/O system is made up of (1) controller, which controls such features of the ripheral device itself as electronics for print-head lection, paper motion, and print timing; (2) one or veral buses (the actual lines that connect the devices units); and (3) an interface (the logic circuitry that controls the larger activity required to synchronize data transfer by performing such functions as level conversion, command decoding, multiplexing, and data request logic).[23]

The actual data are transferred by one of two main methods: programmed I/O (PIO) or direct memory access (DMA).[24] All minicomputers have PIO, which is a software technique. Input/output instructions transfer the data and are device-dependent. That is, the instructions are peculiar to each kind of device. PIO is slow and is appropriate for data transfers with slow-speed devices such as paper tape equipment, hard-copy terminals, and low-speed line printers.[25]

DMA, a hardware feature, is not on all minis.[26] It allows data to be transferred at high speed between the device and the memory itself. The DMA interface is sometimes called a channel. This channel contains (1) a memory address register, (2) a word counter to keep track of the number of transfers performed, and (3) logic for gaining access to the memory and providing the necessary timing and control signals. The DMA is used for high-speed devices such as magnetic tapes, disks, and drums. A multiplexer channel is used to handle DMA for several devices. It is somewhat slower than DMA, but it allows a number of data operations to occur simultaneously.[27] The interrupt system described above is also an integral part of the I/O control.

PERIPHERALS

The peripherals are made up of anything attached to the mainframe. Generally classed as input/output devices, they function as mass storage or man/machine interface devices; some can serve both functions.[28]

Mass Storage Devices

Mass storage serves as an extension of computer main memory. The media range from punch card and paper tape to magnetic tape and disks. Each medium has different speed, capacity, and storage characteristics. Selecting the proper device for mass (file) storage is critical to the efficiency of a data processing application.

Periodicals feature surveys of ripherals; for example, "Peripherals Make the Mini; *Modern Data's* Annual Survey of Plug-Compatible Miniperipherals," *Modern Data* 8 (December 1975): 34–43.

Punch Cards

The punch cards contain data represented by patterns of holes punched in the 80 columns of each card.[29] Each column can represent a character. The cards are stored in boxes and can be handled manually — humans can read the interpreted headers and can remove or add cards as desired. Punch cards are inexpensive, but it takes many cards to hold a given number of characters (i.e., records) and therefore a large amount of physical storage space and much manual handling are needed. Data on cards are entered into the system by means of a card reader, which reads the holes and converts them into bit patterns. Card readers are low-speed devices that read 100 to 600 cards per minute. Cards can be prepared by a keypunch machine offline. Computer-driven card punches can be used to punch cards as computer output. Card readers for minis are common and inexpensive. Card punches for minis are rare and expensive.

Paper Tape

A continuous ribbon of paper called a paper tape can be punched like cards with holes representing data.[30] Unique hole patterns in the paper tape represent the symbols. Six-, seven-, and eight-hole paper tape devices are in common use. The number of holes available determines the number of unique symbols that may be coded onto the paper tape. Most paper tape devices provide for extension of code meaning through a technique called shifting. Shifting requires that a special hole pattern be used to indicate the use of upper-case or lower-case shift. A paper tape printing device will recognize the shift codes and take appropriate action. Software in the computer also must recognize shift codes because the symbols can have one of two meanings according to the shift.

The tapes are continuous, unlike cards which are limited to 80 columns. The tape is smaller, more compact, and requires less manual handling than cards. The problem is in editing or correcting errors on the tape. The paper tape readers work similarly to punch card readers but operate at higher speeds, although they are still classed as low-speed devices. Paper tapes commonly are used with minis for storing the simple, basic programs used to sta the CPU.

Cassette or Cartridge Tape

Magnetic tape cassettes that lo audio cassettes are used on minis.[31] T and read sequentially, like paper compact and relatively inexpensive. capacity for a cassette ranges from 1 characters. The cassette tape drive on the cassette. The speed of data tra drive varies from 500 to 1600 chara Once the tape is mounted, little hu required. The drive that advances o is program controlled. Some syste cassettes, one for the program and o file.

Cartridge tapes are similar to hom but operate in binary as do compute They generally have multiple tra length than cassette tapes, which allo capacity. A cartridge drive is requi read the cartridges.

Industry-Standard Magnetic Tape

The common computer tape is ½ netic tape wound on reels.[33] Th formated so that each bit of a cha theoretical "track." A single positio tape is typically divided into eight c an eight-bit code) and a ninth track u a parity bit (a technique used by so for error checking). As with all tap recorded and read sequentially. Re wound in lengths of 200, 600, 1200, a tape drives record data in densities of bits per inch (BPI), and recordin range from 6672 to 9600 characters p

A reel of magnetic tape is con density of a tape is constant, but dete is not always a matter of multiplyi foot times the number of feet. The d recorded in blocks, separated on eac cord gaps (IRGs) which help in sear locate particular records. The num reduces the character capacity of ea

[33] Ibid., pp. 65–67.

of tape can be handled easily and stored manually, and they are relatively inexpensive.[34] Because tape is a sequential or serial device, it is most efficient as a storage medium for data that are to be used in a serial fashion. Inserting new data on a tape requires that a new tape be produced. To locate a record the tape drive winds or rewinds the tape until the data are found. This process is time-consuming and inefficient if data are to be used in a random fashion. The tape drives are considered high-speed devices (the tape is read at up to 150 inches per second), but they are still slower than the internal processing speed. Tape drives can be used singly, but two or three tape drives are more common if the data manipulation requires producing new file tapes or sorting data.

Diskette, or Floppy Disk

Disks are also magnetic storage devices, but rather than being serial and linear like tape, they use two-dimensional surfaces, usually like circular plates.[35] Data are stored on both surfaces, top and bottom, and each surface is divided into tracks, which are concentric circles around the axis.[36] The two-dimensional shape is reflected in the way the read/write heads of the drive operate; they can move or be positioned over any part of the surface of the plate (that is, over any track), which allows direct or random, as opposed to sequential, access. This freedom allows greater speed and flexibility in accessing stored data.

The simplest disk medium is the diskette, also called the floppy disk. This single, flexible (hence "floppy") plate is made of a Mylar material. A paper or plastic envelope or jacket houses the disk and is never removed, even when the disk is mounted on the disk drive. The disk is rotated inside its jacket, and a slot in the jacket exposes the tracks to the recording head. Floppy disk drives vary in sophistication and cost from low-speed, low-capacity units to high-speed, high-capacity units with a top capacity of 350,000 bits and a transfer rate of 1.2 million bits per second. Disk drive units are commonly sold for one, two, three, or four floppy disks. The choice depends on the application.

Fixed-head Disk

These disks are rigid, circular plates and are than diskettes. The read/write heads are desig that each track has its own head. The pr determines which track to read. Disks are the mass storage medium, but not the largest in s capacity, and are more expensive on a co character basis. Fixed-head disks are mounted in ually, like floppy disks, and are used in multiple application warrants.

Movable-head Disk

A movable-head disk is so called becaus read/write head moves across the disk to the desired.[37] Then the data are read or written. Th it takes to move the head makes this type slowe fixed-head disks, but once the head is located o track the data transfer rate is the same. Movabl disks are generally packaged with multiple dis unit.[38] A disk cartridge usually has two o surfaces, and disk packs have 10 or 12 surfaces surface has its own read/write head mounted arm assembly. This arm moves as a unit when a is selected, which means that if one head is ove two on one surface, all arms are over track two surfaces. This amount of data — one track o from each disk surface — is called a cylinde storage capacity of each unit can vary up to mor 20 million words.[39]

Man/Machine Interface Devices

Man/machine interface devices are so nar avoid confusion with the general class of perip called input/output devices. In computer jarg I/O device is anything that introduces digitize into the mainframe (CPU and main memo processing[40] (1) from the mass storage devic reintroduces the data, (2) from another system telecommunications line, or (3) from a terminal with a keyboard to allow a human to introduc into the system. To the layman, input is not def broadly; it means converting source or huma into machine-readable form and transmitting i computer for storing and/or processing. The

several ways to categorize man/machine interface devices: low-speed or high-speed; hardcopy or softcopy; offline or online; batch or conversational; input only, output only, or a combination.

Punch Cards

Punch cards as a man/machine interface function as described in the mass storage discussion. Keypunch machines are used to convert the source data into card format. The machines are slow and costly in staff time. An average speed is 6,000 keystrokes per hour. One article states that no new system should be designed around keypunch machines.[41] The use of punch cards for transaction records or reentry records still does have merit, however. The card reader usually is used as a remote batch terminal and, as described earlier, is a low-speed device. It can be used for input only. The card punch must be used for punch card output. This use would be limited for mass storage or reentry documents, such as those used in serial and circulation systems.

Paper Tape

For converting source data to machine-readable form, paper tape punches like the Flexowriter are just as outdated as the keypunches. (Paper tape is sometimes combined with Teletype units; this will be discussed later.) Paper tape does not have the transaction or reentry capabilities of punch cards and is not human-readable. The readers are faster than many card readers (2,000 characters per second for the top of the line) but are still considered low-speed devices. Paper tape can handle upper- and lower-case characters but must use shift codes, which slow down conversion and make software more complicated. Paper tape punches driven by the computer are suited only for mass storage or for interface with other systems.

Key-to-Magnetic-Medium Stations

The two main types of key-to-magnetic-medium stations are key-to-tape and key-to-disk stations.[42] There are now key-to-cassette-tape units and key-to-floppy-disk units. These stations can be used as standalone, independent units or in a multistation configuration with a shared processor. They operate offline from the host computer. The input data are gathered and then read into the host system in a batch. These stations can be used for key-to-mass-st purposes if their output is compatible with t mass storage device(s). Multistation units input into a single storage medium (e.g., tap

Because input generally must be sequenc or as it is entered into the host system, mu key-to-tape units are not as efficient (it is d control the input from the various stations t the proper sequence) as multistation key-to-c Originally called keypunch replacement eq key-to-magnetic-medium stations have ma capabilities than keypunches. They perfo functions as error deletion, editing, format merging new and old data. When the shared in a multistation key-to-disk unit is a microc more functions can be performed, especial area of arranging data into formats: po generation of blank or skip fields, left zer duplication, and code conversion.

Transaction Recorders

A number of devices are used to capture d source or point of contact.[43] They make use c prepared material, although not all can l reentry records. A light pen that reads ba ("zebra") labels is one example. A unique r assigned to each item (e.g., order, book, projector) and is recorded in a machine-rea that is part of the data base. The num expressed in unique patterns that are printed affixed to the items. To record a transactio pen is passed over the label and the p translated into electrical impulses, which are against a reference table. The number is th mitted to the mainframe for processing. One optical-character-recognition (OCR) wan online OCR data input from source docu labels) printed in special optical-character-re type.

Some data collection stations read reentr and combine the data to create transactio One type is the badge/card reader used in c systems. The patron's badge is prepunche user's number, and the book informatio already prepared punch card is housed in The data from these two source documents and transmitted along with any preset or keyed data. Several models have different ca

evels of sophistication. IBM produces a number of units, including the 1031, 2790, and 5230.

ers

inters are one-way (output only) devices.[44] They de human-readable hardcopy information, often tches. There are many variations of techniques to ve printed output; each has its particular advan- in cost or quality. There are also many variations e fonts of the printers. Not only is the design of icters quite different, but the selection of symbols able also varies. For example, some printers ot display lower-case data and most cannot iy the diacritics required in library applications. ere are two basic types of printers: impact (where r carbon is caused by pressure to adhere to paper) ionimpact (where electrical or electrostatic mech- is are used).[45] The simplest impact printer is erial or character printer which is basically a uter-operated typewriter. The characters are ed one at a time, and these printers are very slow 180 characters per second).

ie printers are so called because they print an line at a time instead of a single character. This omplished by using multiple print "heads" or nts. A drum, or print wheel, printer is composed many print wheels as there are possible character ons in a line.[46] For example, if 120 characters per vere possible there would be 120 rotary print s, each with all the possible characters, each le of rotating independently, and each with its iammer mechanism. At the time of printing, all rint wheels would be positioned to represent the to be printed in the line. These devices print 150 lines per minute. Because of the inherently d dimensions of a drum wheel, these printers are y limited to upper-case fonts only. Further, the is generally of lower quality due to poor ient (the lines usually wave).

iin, or train, printers generally provide the best quality at the highest speed.[47] In this type of r, the print mechanism has a continuous chain of cters which rotates between the ribbon and ering mechanism. The number of hammering ins determines the number of print columns that e displayed — most commonly there are 132 characters per line. As a character passes in front of t hammer for the column in which it is to appear, t hammer is activated and the character is press against the ribbon, leaving the impression of t character on the paper.

Because chain printers have separate hammers each column of print, it is possible to increase the spe of print by increasing the availability of characters the chain. That is, if the chain contains the compl set of symbols a single time, each hammer positi potentially could require a complete chain revoluti before the character it requires would appear before By increasing the chain to two complete sets symbols, the maximum number of potential rotatio is reduced by half.

There are limits on the physical length of the cha which limit the number of complete sets that can placed on the train. Also, the number of symbols to represented affects the number of character sets a therefore the speed. Printers with limited fonts a faster than those with more extensive fonts. Typi printing speeds for minicomputer chain printers a 100, 200, 300, and 400 lines per minute. Speeds excess of 1,100 lines per minute generally are limited large-scale computers.

Impact matrix printers use rows and columns wires, the tips of which compose a matrix of dots, construct the print images. Each character is rep sented as a specific arrangement of dots, produced extending the appropriate wires in the matrix agai an inked fabric ribbon to print the characters paper. Common units have 120 characters per line a print at a rate of 500 or 1,000 lines per minu Nonimpact dot matrix printers commonly use a he sensitive print head. A matrix of dots composes t characters. The dots are produced by electrica charging the wire tips, which darkens a special he sensitive paper, leaving the outline of the symbol.

Interactive Man/Machine Interface Devices

Interactive man/machine interface devices are class in themselves in that they must meet cert requirements. An interactive terminal must han means for inputting information and displaying inf mation back from the mainframe almost immediate To be interactive means to be under direct control

information on printing and printers, see: Irving L. Wieselman, "Printer Technology and Its Future; A Printer Primer," *Modern Data* 8 (November 19 an M. Bowers, ed., ["Computer Printers] Manufacturers' Data," *Modern Data* 8 (November 1975): 43–45; Dan M. Bowers, ed., "Printers and Teleprint *o Systems* 10 (January 1977): 30–53.

es and Becker, *Handbook of Data Processing for Libraries*, p. 318.

rnational Business Machines, *Student Text Introduction to IBM Data Processing Systems*, 2d ed. (White Plains, N.Y.: International Business Machines C l Publications Department, 1968), p. 57.

the CPU. To be online means that the transaction is going into the system and being processed at that time (as opposed to batches of transactions gathered and entered later). It often means being in a time-sharing environment with multiple users.

To be conversational means that a dialog is being executed between the man and the computer programs — questions are asked and answered; prompts are given to aid and control the input; errors are detected and corrections accommodated on the spot. As a group, interactive terminals are not suited for high-volume capability — for either input or output. An individual, one-transaction-at-a-time mode is the most common and most efficient.[48]

Keyboard/Printer Terminals. The most common interactive terminal, and indeed the most common peripheral used on minicomputers, is the Teletype.[49] The Teletype unit is made up of a keyboard and a typewriterlike printer.[50] The keys print in response to the manual keyboard or on signal from the computer. The Teletype is a low-speed device that performs serial data transfer (one character at a time) with full or half duplex transmission. The speed is 110 BAUD for the transmission or 10 characters per second for printing. The input rate is limited by the speed of the keyboard operator, which averages about four characters per second. The Teletype controller converts the serial data into parallel for transfer to the CPU and back from parallel to serial to transfer data from the CPU to the Teletype.

Teletype units come with various options. Some are equipped with punch tape reader/punches, allowing buffer-type input, which can increase the rate of input and allow offline data preparation. Some are equipped with faster printers, such as ball-type Selectric printers.

There are other manufacturers of keyboard/printer terminals, and their units vary in options, functions, speed, noise, and cost. Some are portable and are equipped with acoustical couplers to allow telephones to be used to connect to the mainframe. Some use cassette tapes for even more sophisticated buffering; this type of terminal allows a permanent hardcopy record of the dialog with the system as well as any formated output product, such as a printed table, stencil, etc.

Keyboard/Display Terminals. The display terminals is "softcopy," or images that appe cathode-ray tube (CRT) screen.[51] The prir similar to that of a television set where el impulses are painted on a screen by a "gun." T two types: alphanumeric and graphic. The a meric type uses a matrix on a mask to for images on the screen. Only a predetermined c set can be displayed; some CRTs can display case letters only, some can display upper- an case letters and a few special characters, an few can handle diacritics.

In general, CRTs are more flexible, fas quieter than printers. CRTs have a great capabilities and sophistication. The simp nothing more than Teletype replacements. character-oriented, receiving and transmitt character at a time. In fact, these CRTs plug TTY control board, and the mainframe is that the device is not a Teletype. Data are d faster on the CRT than if they were printe TTY, because the print mechanism does no down.

The various features or options a CRT c include the ability to "buffer" characters int for faster, more efficient transmission and the display an entire page at once instead of u "scroll" method, which displays one line at a ti the bottom of the screen up (pushing the to when the screen is full and a new line is displ CRT may have a cursor, or special symbol, t appear as an underline, a reversed image char other symbol superimposed over a line posit indicates the current operative position on the can be spaced forward or backward to pos next character to be input. Another CRT fea directional-controlled cursor combined with nal memory to perform edit routines such as

1. Character deletion (the ability to dele more characters from the CRT memory)
2. Character insertion (the ability to inse more characters in the CRT memory)

Reynolds, ed., "Alphanumeric Display Terminals; Part Market and Technology—Where They Stand Now," *Modern Data* 9 (February 1976): 44–51; Barbara A. Reynolds, ed., "Alphanumeric Display Term Who's Who in CRTs and Where the Market Is Going," *Modern Data* 9 (March 1976): 44–51; Radwin, "Choosing a Terminal; Part 1," p. 11; Radwin Terminal; Part 2," pp. 61–73.

3. Character substitution (the ability to substitute characters in the CRT memory)

to move to any location within the screen in a mat mode to enter data, as with a form to "fill out" data input. A CRT may also have program-ntrolled use of visual effects such as reverse video, nking, and foreground-background contrast (high d low intensity). CRTs vary in number of characters r line and number of lines per screen. Some CRTs ve no control functions at all and are controlled mpletely by the CPU. Some have some control nctions that are hardwired (for example, function ys). Some have chips (ROMs or PROMs) that have edetermined control functions. Some have address-le internal memory and logic to be user-pro-ammed by a programming language.

The CRTs slide over into the category of intelligent rminals or even microcomputers. Some key-ard/CRT terminals have the ability to have an ditional peripheral "hung on" to them. One com-on option is a printer, so that what is displayed on e screen can be printed on request. Input devices ch as OCR wands or light pens often are combined th keyboard/CRT terminals for special applica-ns.

Intelligent Terminals. The term "intelligent termi-l" is used in many ways. The following are often lled "intelligent terminals": programmable interac-e CRT terminals, shared processors for multistation y-to-disk systems, and small, single-application nicomputer or microcomputer systems. For the term be accurately applied these minimum characteris-s must be met.[52]

- Self-contained storage; random access memory
- User interaction with the terminal itself
- Stored program capability
- Processing capability at the terminal through a user-written program
- Capability of online communications with another intelligent terminal
- Human-oriented input, such as a keyboard
- Human-oriented output, such as a printer or a CRT

telligent terminals allow some point-of-source, or cal, processing. Small files can be accessed on the ot before data input. An intelligent terminal can perform expanded editing functions, and data commonly are transmitted to the mainframe only when completely edited. Also, intelligent terminals often perform the communications control functions, freeing the mainframe processor for other tasks.

Input/Output Connections

In the most basic minicomputer systems, the peripherals are connected to the mainframe by cables or hardwire lines because the mainframe is small and usually located close to the peripherals. Even when the terminal is in another room, a cable connection can be made. Theoretically, there is no limit to the length of the cable or the distance between the peripherals and the mainframe, although some devices have maximum limits. Over great distances, boosters or repeaters are used to amplify the signals.

There are times when a direct cable connection is not feasible; instead, data communications or telecommunications are used.[53] That is, the connection is made over telegraph- or telephone-type lines. The computer signals have to be formated or structured so that they can be transmitted over these lines. In most cases, the lines handle analog-type frequency waves, and the digital signals must be converted. A modem (modulator-demodulator) or data set is used to convert the signals at each end. The transmission must match the bandwidth and the range of allowable bit rates of the line.

The mode of communications can be asynchronous (start-stop) or bisynchronous (binary synchronous), and the transmission can be duplex or half-duplex (one-way or simultaneous two-way communication). The connection of the lines can be on a switched or nonswitched (point-to-point) basis, and contact between "stations" can be established through a contention system or a polling system. The entire data communications process requires special I/O controllers, interfaces, channels, acoustical couplers and/or modems, proper CPU instruction sets, and special systems software.

SOFTWARE

Minicomputer software has been notoriously lacking for general consumption. Until the last 2 or 3 years, a limited amount of software was commercially

[52] Robert O. Ritchie, "Intelligent Terminals and Distributed Processing," *Computer Decisions* 7 (February 1975): 38.

[53] For a general description and glossary on data communications written especially for librarians, see: Mark S. Radwin, "From Nodes to Modes-Duplex and lf-Duplex," *Online* 1 (January 1977): 13–19. For more detailed descriptions, refer to technical manuals such as: International Business Machines, *IBM System/360 rating System Basic Telecommunications Access Method,* 3d ed., IBM Systems Reference Library (White Plains, N.Y.: International Business Machines Corp., Data ocessing Division, 1968), pp. 9–17.

available; most had to be prepared for each system application. System software provided with the equipment was often sparse, and additional modules had to be purchased as options. This condition has changed somewhat, but on the smaller systems (such as microcomputers) there is still little comprehensive software available.

The amount of software available affects the development time in preparing an application system. The sophistication of the system software can affect the uses of an installed, ongoing system, even though much of the support software is for use by the programmer/designer.

There are two basic kinds of software: systems and applications. Systems software is an umbrella term that covers programmer-support software, assemblers, compilers, and operating systems. Application software includes general-purpose packages and the final user-specific program.

SYSTEMS SOFTWARE

Corey explained minicomputer manufacturers' software, starting with the simplest versions and moving to the most complex.[54] He classed the simplest software as being made up of four programs: the bootstrap loader, the loader, the assembler, and the debugger. The GML *Minicomputer Review* lists the minimum programs for a minicomputer as diagnostics, binary loaders, debugging and utility routines, and editors.[55] The most basic types of programs are used by the programmer to make the hardware work and to create a new program.

Program Development Aids

Assemblers

An assembler relieves the programmer of the task of coding a machine language program in binary or octal.[56] The assembler translates a rather low-level mnemonic source language program into an object language program, which is the machine language — usually on a one-for-one, instruction-for-instruction basis. The object code is expressed in an absolute address (that is, a specifically assigned memory location). An enhancement available for an assembler is production of a relocatable format or addi be loaded into and executed from any a memory.[57]

Some manufacturers have, as an option sembler. For this type of assembler, the mnemonic codes for operations represe instructions in machine language. A macr a formal sequence of coded instructions evoked, results in the entire sequence bein machine language.[58] The length of the memory is not shortened but it does save programmer's time. Cross-system assemble able from some manufacturers.[59] These actual assembly of minicomputer prog performed on a large-scale computer syste mounted on the mini for execution. Th faster and more efficient and can save me mini.[60]

Loaders

The computer hardware "knows" not how to use a program, and not even ho input of the program.[61] When a mini turned off, or powered down, it returns to t state. A hardware device can be used to l with a program, or a software progra bootstrap loader can be used. The bootstr used to specify the data to be deposit memory address where the data are to go program and actually is used to load the relocatable loader program, which is a l comprehensive system program used by t mer to load programs into the memo When this loading is complete, the con over by the regular (i.e., newly loaded) linker-loader or a linkage editor is used t internally of where the various programs a main memory and allows them to be modules as required for a total program.

Editors

An editor is of value in creating progra command words and the instructions th allow the programmer to create a new pro accurately to enter a new program previou

coded) with aids and prompts or to make changes he program previously written without starting n scratch (without reassembling). One type of or is the line editor which allows lines of the source gram to be added, deleted, or modified.[62] Another is the string editor which allows the programmer dd, delete, or modify character strings. The most prehensive is the text editor which retrieves lines of from a file, allows the programmer to correct the by inserting or deleting characters or whole lines, returns the corrected lines to the file.[63] Text ors are used online in an interactive mode, which is most sophisticated mode.

uggers

debugger program helps the programmer deter- e what is wrong with the program. Although the mbler can check for and detect syntactic errors, cal errors are usually found only when run on the puter.[64] The debugger program allows the pro- mmer to view the internal processes and conditions he computer as the program is run. For example, if program stops due to a fatal error, the debugger gram provides "extensive information about the of the machine at the time of the failure."[65] An ne, or dynamic, debugging program allows the grammer to perform the following tasks.[66]

Start a program
Suspend its execution at predetermined points
Examine and modify the contents of memory words and registers
Make additions and corrections to the running program using either symbolic or octal code

s is the most efficient way to debug a new program epair problems in an existing program.

gnostics

diagnostics program is used to test the equipment determine if it is functioning correctly. It can be l as part of a maintenance procedure or, if blems have arisen, to determine if there are dware stresses or malfunctions or memory stresses problems and to locate and identify the problem s.

Utilities

Utility programs are programmer aids that handle certain recurring functions, such as[67]

- Moving data from cards to tape or vice versa
- Moving data from cards to disk or vice versa
- Moving data from tape to disk or vice versa
- Moving data from cards, tape, or disk to the printer.

These programs generally perform such routine operations as moving, printing (listing), or dumping data, which can be performed without manipulation or any recognition of specific file format. For example, an 80/80 listing is one in which data on 80-column cards are printed as punched. The programs also perform general system maintenance, such as disk space allocation, system utilization accounting, and construction of program libraries.

Subroutine Libraries

Some small programs or subroutines are written to handle mathematical functions and are called up or linked to the application program as needed.[68] The common ones for minis are for fixed-point arithmetic (multiply, divide, double precision), floating-point arithmetic, conversion of data formats (decimal to binary, fixed point to floating point), and trigonometric functions. These are especially important in minis because they enable software options to replace unavailable hardware features.

Compilers

Although a compiler is definitely a program development aid, it is not a requirement of a support software system. A compiler is similar to an assembler in that it translates a source language into object, or machine, language. Compiler languages are higher level and often designed to be used on any type of machine. The common standard languages are FORTRAN, BASIC, and COBOL. Each is designed for a certain area of application: FORTRAN is designed for scientific applications and any other area requiring high-level mathematical computations; COBOL is a business-oriented language and handles words, text, etc., with great input/output and file format flexibility. Some manufacturers have created their own high-

level languages and compilers to best suit their own equipment (for example, DEC's DIBOL).

Each language has a set of standard words or instructions that represent common functions or routines — these are similar to macro-assembler instructions. Working storage control is handled by the language conventions, as are file definitions and file handling. Compilers have checking features to diagnose programmer errors in language use, including errors in both semantics (meaning) and syntax (form).[69] Error messages are displayed so the programmer can correct the source code and the program can be recompiled into executable object code.

Compilers are used in several modes. The source program can be compiled once and stored ready to execute. The source program can be compiled and then immediately executed (this is called compile-and-go). Some compilers are in the interpretive mode, where each statement is individually executed. (This mode is typical in conversational language compilers. A common interpreter is in BASIC specifically designed for interactive programming.) Compilers take space in main memory and use main memory as working storage while executing. Some compilers can be used only on CPUs of certain minimum sizes. One source states that BASIC and FORTRAN compilers require a CPU with 4K to 12K memory, while a COBOL compiler requires 8K to 16K memory.[70]

When compilers remain resident in memory at all times, a system designer must allow additional memory for the other programs and data, or the memory would be compiler locked (bound). As stated earlier, compilers are not necessary for systems. Without a compiler the programmer could code the programs in assembler language. More effort would be required (more lines of instruction, more file and memory location control, and less subroutine use, as well as more programming expertise in general), but often a more efficient program can result with maximum use of the CPU and main memory for that specific application.

File Management Programs

ımed system control. It communicates with the ator to request parameters or to report status; , links, and sequences programs for execution; ns I/O devices to programs; performs all I/O ations; and services interrupts."[75]

complete operating system requires a mass storage e to store programs and data, and each type of storage device requires its own specific type of ating system. Thus we have cassette tape operat- ystems (CTOS), tape operating systems (TOS), operating systems (DOS), and virtual (memory) ating systems (VOS or VS).

ıe heart of the operating system is the supervisor, onitor, a master control program that remains ent in memory.[76] It is responsible for initiation, tenance, and termination of all other programs. ocesses the communications among the user, the m, and the many control programs. It also acts on tor calls, validates and transmits I/O calls to e handlers, supervises data and file manipula- , and provides error diagnostics. A main service ided by an operating system is file maintenance, ially in the area of creating and maintaining a tory that contains the location of all the files ntly used by the program.[77] It also protects files at data are not destroyed inadvertently.

erating systems are organized differently and ion differently according to the mode of opera-

Simple executive, single process. This kind of system is designed to handle the program interrupts and I/O control for one single application for one user.

Single batch.[78] Batch processing is a technique in which jobs are collected and grouped before processing. A single batch operating system links serially the functions or programs required to perform one entire procedure for one user. For example, to update a serials holding file, a read program, a sort program, a file maintenance program (to update the file), and a print program may have to be used sequentially. The single batch operating system would handle the execution of these programs with little human intervention.

3. *Multiprogram batch.* This operating system allows several jobs or more than one batch stream to be run "at the same time." This seemingly simultaneous processing of several programs is produced by the operating system's ability to transfer control of the CPU between programs. For example, when one program must await the completion of an I/O request, the other program can be executed by the CPU. Additional sophistication is achieved when an operating system has a feature for "quantum" or time-sliced program execution. Time-slicing involves establishing a fixed quantum of time for the execution of each program, and when the quantum expires, the operating system transfers control to a different program already resident in memory.[79]
4. *Online interactive.*[80] The essence of an online environment is that the input data enter the computer directly from the point of origin and/or the output data are transmitted directly to where it is used. Processing occurs in a single transaction as opposed to being deferred and gathered with other transactions to be processed in a batch. This process requires the operating system to perform a different kind of control and sequencing, because there is not always a predetermined sequence of jobs or programs. Rather, the jobs are determined by the user at the time of input or during processing through a conversation or dialog.
5. *Time-sharing.* This process allows multiple users to share system resources in such a way that each thinks he is the sole user. Time-sharing combines the multiprogramming concept with the online interactive mode. The computer handles several jobs in a dynamic state by jumping back and forth between programs as required. A time-sharing operating system is made up of a sophisticated set of control programs "to handle the sharing of system resources, the time-slicing, the storage allocation and program relocation, and the basic servicing of the users, besides the types of operations normally associated with an . . . operating system."[81]

APPLICATIONS SOFTWARE

To the user of the computer system, the only software of interest is that which allows his data to be processed to accomplish his or her objective. This user-specific, application-oriented software is developed through the use of the systems software and made functional by means of the operating system, but the success of the project depends on the responsiveness, efficacy, and efficiency of the applications software itself.

Applications software is the end of the systems analysis/systems design/systems development process. The flow charts and decision tables become more specific to the application, until a programmer can take the material and write the actual programs. The analyst/designer will have determined the hardware configuration, the system specifications, the files and file structures, the operating mode, and the system software that can be supplied. The programmer then uses any or all of these to write and debug the final module.

Sometimes it is more efficient to base the final module on a general purpose software package that can be purchased from the manufacturer or an independent software vendor. These packages vary in what they cover and to what degree they cover the function. There are total, comprehensive data base management systems such as TOTAL, and there are business application packages that provide 80 to 85 percent of the programming with the remaining 15 to 20 percent to be done by the user to achieve a user-specific module. There are also expanded packages for text-processing, search and retrieval, and data communications. The programmer must decide if and when a general purpose package is useful.

Another option is the use of a complete, turnkey applications package that can be purchased. A special-purpose package requires the user to provide only his own format details and information. The problem is locating a module that meets all of the system specifications for the user's needs.

CONFIGURATIONS

As stated previously, the specific components of a minicomputer system are determined by the application. Four main types of configurations are appropriate for the library environment: a network node (often an intelligent terminal), a data communications node, a data collection station, and a standalone station.

In general, an intelligent terminal
node has a small main memory and

Class II minicomputers can handle more general plications for single users. Manipulation capabilities clude tabulating or summarizing data from specific lds in the records of the file; searching and printing ta; and outputting in the same sequence as on the e but with the data reformated if desired. No sorting possible. The CPU has either 8-bit words and up to K main memory or 16-bit words with up to 32K ain memory. The I/O control can handle both ogrammed I/O and DMA. Three I/O devices can supported: usually one man/machine interface vice, such as a buffered CRT or a Teletype and inter, and two mass storage device drives. This class minis can operate sequential files with paper tape, nch cards, tape cassettes, or magnetic tapes; or it n operate a direct-access file on a floppy disk (with to two drives). The only communications link ssible is a direct line to a host computer. The support ftware is somewhat more complete than that of Class the operating system is either a simple executive, ngle-process system that must be totally attended, or single batch system in which one job stream can be mputer-controlled. The operating system type de- nds on the mass storage device, e.g., tape or diskette. he compiler can be for BASIC or FORTRAN.

Class III minicomputers are general-application stems for single users. They can handle single or ultiple batch operations. The processing can handle rting and any other manipulations possible in a tch mode with a quite large file capacity. The CPU s 16-bit words and up to 64K main memory. As any as eight different I/O devices (or devices and drives) can be supported, and concurrent communications are possible with a host computer over a bisynchronous line. Mass storage devices can be tape cassettes, magnetic tape, or floppy disks. The operating system would handle multiprocessing for distributed networking.

Class IV minicomputers introduce interactive processing for multiple online users with a single application. They offer great versatility in manipulations such as sorting and searching. Users can be remotely located because there are four to eight asynchronous lines and the software necessary for controlling the telecommunications. The CPU has 16-bit words, and the main memory is either 128K real memory or 64K virtual memory. The input/output controller includes PIO, DMA, and a multiplexer. The mass storage devices now can include disks (fixed-head platters, movable head disk cartridges, or disk packs). The operating system will probably be DOS (if the big disk devices are used) or VOS and an online, interactive type. The compiler can be for BASIC, FORTRAN, or COBOL. The system software would be a complete complement.

Class V minicomputers are the largest, most sophisticated systems. They can handle time-sharing for multiple online users. They have large file capacity and are very powerful. The top end of this class overlaps large-scale computer classes. The CPU has 16-bit words and 64K virtual memory. The operating system would be a VOS of a time-sharing type. The system software would probably include a data base management package.

CHAPTER FOUR: MINICOMPUTERS—LIBRARY APPLICATIONS

TEM SELECTION: THE DGE

n the variety of minicomputer components, s, and features to choose from, how does one he proper system? Selection must start with the c application and its requirements. A bridge e built connecting the specific requirements of a r operation with the detailed specifications ed for an RFP or a contract. This bridge must lt each and every time a library chooses a system e each library's requirements differ from those ers. Every bridge is supported by five columns : 11): (1) design characteristics, (2) hardware ts, (3) software impacts, (4) library system cations, and (5) the specific class of minicompu- quired. The following sections describe the s of erecting these columns.

UMN ONE: DESIGN RACTERISTICS

ooking at a potential minicomputer application en automation in general), the first review must conceptual terms that ignore the specific tasks ed.

design characteristics of a system can be broken into six categories, which are not necessarily e:

- Ieans of inputting
- ypes of output products
- ile structure and size
- ransaction/volume
- Applications characteristics
- Interfaces to other systems.

These design characteristics are not definitive. Not all will be of interest in all applications. The categories represent, however, the kinds of considerations that arise in system design. Table 12 lists these considerations in detail.

TABLE 12—Design Characteristics

INTERFACE WITH OTHER SYSTEMS
- Offline interface
- Online interface
- Links to multiple systems

Means of Inputting

The input to a system involves getting the data from its source into the computer — from human-readable form into machine-readable form. This is where the human interfaces with the machine. The real impact of any automation effort is felt here first and cannot be eliminated entirely. The best that can be done is to make the means of inputting as efficient as possible.

Input in its larger sense includes the entire data handling process: data capture, transcription, keying, verification, error correcting, and sometimes transmission for processing. It has been estimated that up to 50 percent of a data processing budget can be involved with data handling. This proportion is true for the library also. Cox, Dews, and Dolby wrote that "in a computer system, the most time-consuming and expensive single operation is probably the original preparation of the data in a machine-readable form."[1] Ways to reduce the costs include reducing the amount of manual handling and rehandling of the same data, increasing the ease of both data "keying" and data editing/correction; and increasing the speed of data "keying," "reading," and "transmitting."

Attention must be given to the impact of the inputting on the computer system as well as the impact on the library staff who must perform it. Sometimes the two areas conflict, and compromises must be made.

MEANS OF INPUTTING
- Nature of the data
- One-way or conversational input
- Combinations of input devices
- Location of input stations
- Multiple online users
- Outside sources

Library data are quite complicated in data p ing terms. They are mainly alphabetical with re ments for upper and lower case, special characte as diacritics, and different type fonts such a light, and italics. Hayes and Becker point out the library a number of major categories of data compiled: management data, circulation data loging/indexing data, selection/acquisitions dat textual data.[2] Analyzing the nature of the involved in the new system may dictate the use o equipment or militate against the use of other d

One-way input involves transmitting data computer without receiving transmission back time of input. One-way input generally is use batch processing. The initial data conversion ment is prepared offline, and the data are ga into a group or batch and then read or entered i system as high-volume input. Another form of o input is the use of a light pen to read bar code la an online mode. Although a light is often used t an indication that the data were received, this r is basically one-way as opposed to conversationa

Conversational input is a feature of an inte processing mode. Input often is in the form of a between the user and the program. Questio asked and answered, display forms are fille problems are noted and corrections prompte type of input requires a device that can handl way communications — both input and outpu method can ease the editing and error-cor problems of input, but it is slower and in some s ties up the CPU. If the volume of input is heavy bind up the system if precautions are not taken.

Sometimes applications call for the use of mo one type of input (for example, a light pen p interactive terminal for circulation, a card rea reentry records and a key-to-tape station for a system, or a magnetic tape reader for MA distribution tapes and an intelligent termi cataloging input). Each device is used one at

[2] Robert M. Hayes and Joseph Becker, *Handbook of Data Processing for Libraries,* 2d ed. (Los Angeles: Melville Publishing Co., 1974), pp. 278–9.

he fact that there is more than one type must be idered.

ne physical locations of the various input stations must be considered. If the input is handled at a t next to the mainframe, one kind of connection is er. If it is handled at a remote location, more isticated connections may be required.

more than one user must enter data at the same , the system must be designed to handle more than input line. This problem occurs in the online ractive mode and is really a sophisticated require-t. From the user's standpoint, however, it may be ey to a truly useful system.

ecause of the time and expense involved in data ersion, it is important to enter information in hine-readable form available from outside sources never possible. Input may be in an online, puter-to-computer, or an offline, read-on-request ronment.

es of Output Products

ne output products of a computer system make the ts of data processing available for use by humans another computer system. The form of the output the amount, format, sequence, frequency, and nanence of the information supplied by the puter all have bearing on the system itself. As with t, the special requirements of library data must be idered in selecting output devices. It is important the products called for be thought out carefully in s of the new system, and that they not be mere cations of current manual products. For example, ere any need for a weekly books-on-order list if the rder file is available through online, direct access y time?

- Combination hardcopy and display
- Machine-readable

ne best known type of hardcopy output is the 11-4-inch continuous-form printout produced by a puter-driven printer. Other types of hardcopy ucts are appropriate for some applications: card-, stencils, multipart forms, standard 8½-by-11 stationery, and 2-, 4-, or 6-up continuous-feed r. The quality of the type can be critical. Most copy output is used internally by the staff and for ed periods of time, but such products as computer-uced book catalog pages and catalog cards are more permanent and are used by the public; they require greater legibility and better esthetics. If large amounts of hardcopy output are required, the speed of the output devices becomes critical. The system can be output-bound if the devices are too slow.

Display output (a visual image on a screen) is often used in online, interactive systems. It is usually combined with a keyboard device as an interactive terminal. The display device must match the requirements of the nature of the output data and the requirements of the system in expressing or formating that data.

A combination of hardcopy and display output is used when there is a need for a permanent record or a special hardcopy form in an online interactive system that uses a CRT-type keyboard/display terminal for conversation. A printer is combined with the CRT/keyboard unit, sometimes for simultaneous output and sometimes as a print-on-request slave.

Machine-readable output is used to allow two computer systems to "talk" to each other. Output from the system also is used to send to other systems for further processing, such as COM production or photocomposition.

File Structure and Size

The intellectual content of the system, the data that are input, processed, referenced, maintained, created, and output, is made up of data elements handled as subfields or fields. Related fields are combined into a complete, logical unit called a record. Similar records are combined into a file. The order of the records on the file is called the file structure. Common structures are sequential, linked, indexed sequential, direct access, and random access.

The type of file structure selected usually depends on the size of the file (extremely large files almost always are maintained on magnetic tape and therefore in a type of sequential structure) and the nature of the operations conducted on the file (the kind of posting, referencing, and updating). A programmer can define the files as required for the most efficient processing for the application. There are different types of files: master files, transaction files, input files, output files, intermediate files, and reference files. One enormous file can be defined if desired, or a series of files can be defined with no redundancy and linked into an integrated data base. The way the files work against one another during processing also must be considered. In any case the files do affect the computer design-

FILE STRUCTURE AND SIZE
- Structure
  - Sequential
  - Direct Access
- Size
  - Total number of characters
  - Number of characters required at one time

A sequential file can be handled on any type of mass storage device. The device selected depends on such elements as speed, ease of handling, and cost. Sequential files typically are used in the batch mode.

A direct access file generally is used in the online interactive mode and can be handled only on a disk-type mass storage unit: floppy disk, fixed-head disk, or disk pack.

The size of a file can affect the system design. Although a hardware configuration can be put together to support an enormous file online on disks, it becomes inordinately and prohibitively expensive. Instead, slower, but cheaper, magnetic tape is often used. Each mass storage device has a maximum capacity, and the size of the file in characters can be used to compute the number of mass storage units required. For an online system, the number of characters that must be accessible at one time can influence the decision about which mass storage device to use.

Transaction/Volume

The capacity of a system, or its total size, is important of course. However, in many cases a more critical consideration is the peak load at any one time. For example, it is important to know the total circulation transactions per year, for counters and statistics parameters, but more important figures are the largest number of transactions outstanding at any one time (for file capacity) and the greatest number of borrowers at any one time (for input device load).

TRANSACTION/VOLUME
- Expansion and growth
- Peaks and pressure points of activities
- Response time

Although minicomputers need not have the lifespan of large-scale computers and therefore do not have to be installed with a capacity to handle long-range future growth, expansion and growth should be considered. Some hardware can handle only one input/output device; some can handle only one user at a time; some CPUs can be expanded to only a certain memory limit; and some I/O controls can drive only as many as four devices. If growth or expansion is required and the hardware cannot accommodat changes, an entirely new system (hardware software) may be needed.

The peaks and pressure points in activities system are of vital concern, but they are very dif to determine correctly in advance as far as CPU time, memory access time, I/O interrupt res time, etc., are concerned. The peaks and pre points must be considered for the man/ma interface devices also. The number of lines of pri required at one time must be used to compute pri time based on different printer speeds. The numb documents to be keyboarded at any one time m used with a unit time for entry to determine how input units are required for one work shift, two shifts, and so on.

Response time must be considered for all syste immediate status information is required, the mode may be eliminated and an online inter system may be needed. Then, with an online sy response time involves the amount of time the waits at the terminal for an answer from the sy Sometimes heavy loads in a time-sharing syste slow down response. These can be in the I/O co memory access, or processor areas. For example, systems are stated to have capacity for eight user any more than four online at a time can slo system down significantly.

Applications Characteristics

What is wanted from the system? What ca system do? The answers to these questions are i tant in describing the application the system will The type of operations to be performed and the n of each must be reviewed.

APPLICATIONS CHARACTERISTICS
- Sorting
- Searching
- Special I/O hardware
- Remote access
- Response time
- Reliability

If the files require much manipulation to so data, this must be considered by the har designer. Also for consideration are the nature data to be sorted (alphabetic or numeric), an number of records to be sorted. The solution t sorting problem may be to provide a large amou working space in which to perform the sorting provide redundant files, one for each sequence, a

: them, which will increase the amount of mass : required.

en, how often, and by what elements the files are ed are significant factors in systems design. How is to be accessed must be considered in terms of ional mode (batch or online interactive); the criteria (controlled vocabulary, Boolean logic, e text); the number of access points in each , and whether inverted files are used. As the s are made, careful tradeoffs among system cost fficiency and user service must be made. For le, file accessibility only through a controlled ılary (i.e., thesaurus) is a simple, straightforward s procedure, but it shifts to the user the heavy sibility of editing and assigning descriptors at time. Accessibility of the file by any word (e.g., a xt search method) relieves the user at input of ctual decisions, but it requires sophisticated are and software that are very costly to imple-

ıe applications are better served by use of special output hardware. In a library, efficiency in the ıtion application may require a badge/card input station or a light-pen wand for bar labels. als system may require computer-punched 80- n cards for use as reentry records. These special ements must be stated at the beginning.

ess to a system by means of terminals physically ed from the mainframe is called remote access. nit may be in the next room, the next building, next county. Direct line connections can be used me remote access locations, but over longer ces the laws of physics prohibit the use of direct Remote terminals at these distances must be cted by telecommunications lines, and these direct impact on both hardware and software. : response time required varies according to the ation. If critical, response time should be a requirement and considered an application cteristic to be given special attention in the design.

iability is always desirable in both manual and ated systems. Some applications, however, im- tricter constraints on downtime than others; if lity is critical, it should be stated as an applica- aracteristic. The solution may be an alternative al backup procedure; a duplicate, totally redun- computer system; or a second system capable of rocessing.

Interface With Other Systems

As a system is designed, other systems in the same library or agency and in the library community in general should be considered. The ability to interface with these other systems, whether directly or indirectly, must be established if possible. Sometimes the information flow will be one-way, sometimes two-way. (Implicit in this concept is the exchange of data in machine-readable form.)

INTERFACE WITH OTHER SYSTEMS

- Offline
- Online
- Links to multiple systems

Offline interface merely provides a means of transferring data in machine-readable form by physically transporting the medium (i.e., punch cards, magnetic tape, or floppy disk) to another computer to be read rather than transmitting data directly over a communications line.

Online interface allows direct computer-to-computer communications. The communications exchange can be one-way or two-way, continuous or batch.

"Links to multiple systems" is another way of saying distributed networking in which the processors and their operating system software allow tasks and resources to be divided and shared throughout the network. For example, the file used by system A may be a part of, and physically located at, system B. Transfer of data, control of the manipulation, and control of input/output devices are all shared and transferred back and forth as required by the operating systems. These functions are technically complicated but promise greater efficiency and efficacy in the long run.

COLUMNS TWO AND THREE: HARDWARE AND SOFTWARE IMPACTS

When design characteristics have been reviewed, the impact of each is expressed in terms of hardware and software. These columns are interdependent. Often a hardware device dictates a specific software module, and vice versa. Other times a characteristic can be handled by either hardware or software; the choice resides with the system designer and programmer. Table 13 expresses the typical hardware and software impacts of the design characteristics.

TABLE 13—Design Characteristics and Their Impacts

Design Characteristics	Hardware Impacts	Software Impacts
MEANS OF INPUTTING Nature of the Data Alphabetic and/or Numeric, Upper and Lower Case, Special Characteristics,	I/O DEVICE Keypunch machines not suited for special characters, but card readers can handle them. CRTs vary as to what they will handle, but most now handle upper and lower case with a few special characters. Only a few can handle diacritical marks. Tape and disk drives have no limitations.	APPLICATIONS SOFTWARE Must have necessary translation tables to match any character set(s) used.
One-way/Conversational One-way	I/O DEVICE Input only. Ex. keyboard, card reader, paper tape reader, badge reader station, light pen I/O CONTROLLER. Must match device.	
Conversational	I/O DEVICE Two-way; output or response capability. Ex. Teletype or CRT/keyboard unit I/O CONTROLLER. Must match device.	APPLICATIONS SOFTWARE If a higher level language is used, it must have a compiler that supports conversational programming.
Combinations of Input Devices	I/O DEVICE Ex. card reader, CRT/keyboard unit, magnetic tape reader, light pen, paper tape reader, etc. I/O CONTROLLER Must consider different speeds. May have one for each type.	APPLICATIONS SOFTWARE Scheme or technique for input varies (block or line mode, character or record at a time). SYSTEMS SOFTWARE Must support the I/O functions for the different devices.
Location of Input Station	COMMUNICATIONS EQUIPMENT Modem or data set, with telecommunication lines. OR Hardwire lines (with repeaters).	SYSTEMS SOFTWARE Must support telecommunications functions.
Multiple Online Users	I/O DEVICE Two-way; conversational capability. COMMUNICATIONS EQUIPMENT Modem or data set, with telecommunication lines. OR Hardware lines (with repeaters). COMMUNICATIONS CONTROLLER May require a processor.	APPLICATIONS SOFTWARE Could be affected if a single program is to handle multiple users (as opposed to time-sharing. SYSTEMS SOFTWARE Must partition memory and be able to handle multiple users. Must be able to handle telecommunications functions.
Outside Sources Incoming Communications Line	COMMUNICATIONS EQUIPMENT Modem or data set, with telecommunication lines. OR Hardwire lines (with repeaters). COMMUNICATIONS CONTROLLER May require a processor.	APPLICATIONS SOFTWARE Possibly a requirement to reformat. May require a bridge program. SYSTEMS SOFTWARE Telecommunications functions support. OR Simpler technique to emulate a terminal.

TABLE 13—Design Characteristics and Their Impacts—Continued

Design Characteristics	Hardware Impacts	Software Impacts
ANS OF INPUTTING—Continued		
achine-readable Form (Offline)	I/O DEVICE Must be compatible with input (card reader, paper tape reader, magnetic tape reader, floppy disk reader).	APPLICATIONS SOFTWARE Scheme or technique for input varies to match device. SYSTEMS SOFTWARE Must support the I/O functions of the different devices.
ES OF OUTPUT PRODUCTS		
ardcopy		
Upper and Lower Case, Diacritics	I/O DEVICE Printers. Must consider extensiveness of character set or flexibility for interchanging character sets. Line printer is more flexible than serial printer. Teletypewriters are upper case only. I/O CONTROLLER Must match.	
Special forms requirements Ex. cardstock, multipart forms, multiple copies	I/O DEVICE Printers. Must be equipped with a special card platen and card feed. Must accept special forms (e.g., multipart forms with carbon).	
splay	I/O DEVICE CRT unit or Digital Read-Out unit.	APPLICATIONS SOFTWARE Must reflect necessary programming techniques that are device-bound (background/foreground, blinking, reverse video, scroll or block mode).
Character Set	•Must consider the character set available; usually quite broad.	
Size of Display	•Must consider the required number of characters per line and the number of lines per screen for display.	
Features	•Desired features may include foreground/background display, reverse video, blinking/nonblinking.	
Scroll or Block	•Must consider whether display can be shown in an entire unit or block or does it move one line at a time. I/O CONTROLLER Must match device.	
mbination Hardcopy and Display	I/O DEVICE CRT plus printer. May print simultaneously with the display, which will be slow, or may print off the display on demand, allowing fast display and slow printing. I/O CONTROLLER. Must match device.	
achine-Readable		
Outgoing Communications Line	I/O DEVICE Must be compatible to network or host. COMMUNICATIONS EQUIPMENT Modem or data set, with telecommunications lines. OR Hardwire lines with repeaters. COMMUNICATIONS CONTROLLER May require a processor.	APPLICATIONS SOFTWARE May have to provide the software to move the data (actual transmission). Must be compatible to other end and may require a program as a bridge (reformat, protocols standards, etc.). SYSTEMS SOFTWARE May support a communications control processor function.

LICATIONS CHARACTERISTICS—Continued		
liability	Duplicate part of the hardware. CPU: duplicate. I/O CONTROLLER: duplicate. I/O DEVICE: have one or two spares. COMMUNICATIONS EQUIPMENT: have backup lines. Alternative methods I/O DEVICE Have an offline device to gathered data. Ex. punch cards to replace online keyboard. Must be compatible to the total system configuration. I/O CONTROLLER Must match device. CPU Intelligent terminal may handle data input in a local processing mode and transmit when system is up. Total system configuration must be designed to handle this method.	
ERFACE WITH OTHER SYSTEMS		
fline	I/O DEVICE Card reader, paper tape reader, magnetic tape reader, floppy disk reader, etc., must be compatible with input in terms of protocols (density, number of tracks) and format (standard).	APPLICATIONS SOFTWARE Scheme or technique for input varies to match device. May require modules to meet format specifications. SYSTEMS SOFTWARE Must support input/output functions of the different devices.
line	I/O DEVICE Must be compatible with network or host. COMMUNICATIONS EQUIPMENT Modem or data set, with telecommunications lines. OR Hardwire lines with repeaters. COMMUNICATIONS CONTROLLER May require a processor.	APPLICATIONS SOFTWARE Must be compatible with other end. May require modules to meet format specifications. SYSTEMS SOFTWARE Telecommunications functions support, or a simpler technique to emulate a terminal.
k to Multiple Systems Distributed Network)	CPU Large amount of main memory. Sophisticated instruction sets. COMMUNICATIONS CONTROLLER May require a processor. May require a concentrator. COMMUNICATIONS EQUIPMENT Modem or data set with telecommunications lines. I/O DEVICE Must be compatible with the network configuration requirements in terms of protocols (density, number of tracks,) and format (standard).	SYSTEMS SOFTWARE Operating system must handle multiprocessing. Telecommunications functions support.

Table 14—Classes of Minicomputer Systems

Characteristics	Class I	Class II	Class III	Class IV	Class V
CPU	8-bit word. Memory: up to 8K real.	8- or 16-bit word. Memory: 64K (8-bit) or 32K (16-bit) real.	16-bit word. Memory: up to 16K real.	16-bit word. Memory: up to 128K real or 64K virtual.	16-bit word. Memory: 64K virtual.
Number of I/O Devices	Two.	Three.	Eight.	Eight.	Eight.
Mass Storage Devices	Paper tape or tape cassette.	Punch cards, paper tape, tape cassettes, magnetic tape, or diskette.	Paper tape, punch cards, tape cassette, magnetic tape, diskette.	Paper tape, punch cards, tape cassette, magnetic tape, diskette, disk cartridge, or disk pack.	Paper tape, punch cards, tape cassette magnetic tape, diskette, disk cartridge, or disk pack.
Man/Machine Interface Devices	Teletype, paper tape unit, or unbuffered CRT.	Teletype, paper tape unit, plus printer. Buffered CRT.	Teletype, paper tape unit, plus printer. Buffered CRT.	Teletype, paper tape unit, plus printer. Special devices. Buffered CRT.	Teletype, paper tape unit, plus printer. Special devices. Buffered CRT.
Communications	—	Direct line to a host.	Direct line to host for concurrent communications.	Direct line to host, 4 to 8 lines to terminals.	Direct line to host, 8 to 32 lines to terminals.
Software	Assembler or BASIC. Little program support.	Assembler, BASIC, or FORTRAN. Limited program support.	Assembler, BASIC, or FORTRAN. Program support software.	Assembler, BASIC, or COBOL. Full program support software.	Assembler, BASIC, FORTRAN, or COBOL. Full program support software. Data base management package.
Operating Mode	Simple executive monitor (attended).	Simple executive or single batch.	Single- or multiple-batch processing.	Online interactive or batch processing.	Time-sharing online interactive processing.
General Capabilities	Data collection and list; editing but not manipulation.	Summarizing, tabulating, searching, reformating. No sorting.	General applications, including sorting.	Online interactive system for multiple users on a single application.	Time-sharing with multiple users online using multiple applications.

:OLUMN FIVE: CLASS OF ɪINICOMPUTER

The final column of the design bridge is the class of omputer system appropriate to the application char- cteristics. (Column four will be discussed later.) ɪgain, it must be emphasized that these categories are nerely representative samples. The proper configura- ion for any system may cut across several of these ategories for the number of combinations is almost nfinite. The categories are ordered in a hierarchy rom simple to complex or basic to sophisticated (see Table 14).

:OLUMN FOUR: LIBRARY SYSTEM ;PECIFICATIONS

The fourth column, that of assessing the library pplication, can now be discussed. This column, owever, must be left blank in this book. The answers nust come from each individual library. For a library ataloging or circulation system, there are no right or vrong answers to such questions as "How many erminals are required?" "Are remote communications ines necessary?" "Does the output have to be in nachine-readable form?" In fact there is often no one nswer in a specific library setting. Decisions can be ased on tradeoffs or on specific constraints. These lecisions are based on the system requirements drawn ɪp during the systems analysis and systems design hases that precede this task.

;ystem Requirements—One End of he Bridge

As stated repeatedly in library literature and in this ook, systems analysis and design form the keystone of successful automated system. At present they often re performed inadequately. The details of systems nalysis cannot be covered in this book. The suggested nain reference to follow is Markuson et al., *Guidelines or Library Automation*,[3] which was written specifically or Federal libraries.

Markuson presents the major phases of systems nalysis and the tasks involved as follows.[4]

1. Perform preliminary planning and preparation
   - Inform library staff of plans
   - Determine objectives and purposes of system study
   - Survey relevant library automation literature
   - Prepare project schedule, allocate funds, and assign staff
   - Establish documentation standards and procedures
   - Prepare project proposal
2. Analyze present operation
   - Perform descriptive analysis
     - Flowcharts
     - Decision tables
     - Questionnaires, case studies, etc.
     - File analysis: files, records, data fields
   - Investigate conditions imposed by outside environment
     - Agency and local agency
     - Library community
     - Others
   - Identify operations requiring human judgment
   - Identify exception situations
   - Identify management and performance data requirements
3. Define system requirements for automated operation
   - Establish input and output requirements
   - Establish operational and human factors
   - Establish staffing, funding, and time requirements
4. Produce project report
   - Document findings in a project report
   - Review findings with appropriate agency management
   - Report on results to library staff.

The first phase is basically a review of the situation and an assessment of what the problems are. It must be pointed out that an automation project should be directed at a problem or need. No one should think of automating simply because it is fashionable or because equipment is available. Automation should be the means, not the end. Some genuine needs for automating can be classified as.[5]

- Increased volume of activity
- Need for improved control over operations
- Need for improved control over collections

[3] Barbara Evans Markuson et al., *Guidelines for Library Automation; A Handbook for Federal and Other Libraries* (Santa Monica, Calif.: System Development Corporation, 972). Another basic library text is: Edward A. Chapman, Paul L. St. Pierre, and John Lubans, Jr., *Library Systems Analysis Guidelines* (New York: Wiley-Interscience, ohn Wiley & Sons, 1970). For a collection of essays on and a bibliography of library systems analysis, see: John Lubans, Jr. and Edward A. Chapman, *Reader in ibrary Systems Analysis* (Englewood, Colo.: Microcard Editions Books, 1975).

[4] Markuson et al., *Guidelines for Library Automation*, p. 26.

[5] Ibid., p. 8.

- Need for improved service to users
- Need to provide new services
- Need to prevent duplication of effort
- Need to operate within existing staffing patterns or conditions.

The specific needs must be stated and formal system objectives written. These objectives should be stated broadly, then restated as specific objectives.

The second phase involves an analysis of the present system. Systems analysis is defined as "the study of all of the components, operations, data, information and material flow, work environment, etc., that constitutes the existing system."[6] To facilitate this process, various techniques such as flow charting, decision tables, surveys, questionnaires, interviews, case studies, and cost analyses are used. In general, systems analysis requires systematic attention to the following items.[7]

Data. These are the files, records within the files, and fields within the records.

Operations. These are the tasks that are performed in accomplishing some functional objective. Operations include filing, posting information to a file, searching, labeling, etc.

Materials Flow. This component concerns the physical entities with which the library deals. Materials include books, serials, maps, microform, laboratory notes, etc. The materials flow includes receipt, processing, storage, retrieval, and use.

Information Flow. This component comprises all of the communications that relate to how data and materials are to be handled and how operations are to be performed and, as used, means information about the system and does not refer to content of materials. It includes policies, regulations, oral communication, forms, reports, and statistical data about the system.

The third phase is to identify and define the system requirements for the new system. "System requirements are the set of tasks and characteristics that the new system must perform and have."[8] The systems requirements are based on the *demands* (for information, reports, and action) on the system from all sources.

Three cautions must be stated about the systems requirements. First, while the new system requirements will be similar to the present system description, they should not be a reiteration of the exis
It is a mistake to automate a manual system
demands and requirements should not e
same. The problem or need on which the ne
based will trigger some different require
existing system has taken on characteristi
the results of constraints that have be
pragmatic adjustments that have been mad
system requirements should be free of thes
bound" requirements and should be an i
ping list."[9] The new requirements shou
drawn up free of existing requiremen
tradition-bound or unnecessary.[10]

The second caution deals with the natur
the requirement. The system requirem
expressed in library terms, "need" terms a
"solution," or automation, terms. For ex
statement "daily access to the order file" v
appropriate library requirement but the
"online file access" would not be — it ste
the "solution," or data processing, area.

The third caution has to do with the
library. Libraries rarely exist as independe
tions. They therefore must be viewed in
within larger structures. The library
requirements are often the first things con
requirements imposed on the system from
library must also be considered. For exam
son lists these aspects of the outside envir
must be considered:[11]

- Agency budget requirements
- Agency personnel or payroll record
circulation or master user files)
- Agency headquarters library policies
- Agency purchasing requirements
- Library of Congress Card Division r
for card purchases
- Vendor requirements for purchase ord
- Agency statistical reporting requireme

Subject to these three cautions, the task
system requirements entails considering t
questions.

- What needs or demands must the s
- What are the impacts (organization
mental, and/or other system) and th

[6] Ibid., p. 29.
[7] Ibid.
[8] Ibid., p. 40.
[9] Ibid.
[10] Chapman, St. Pierre, and Lubans, *Library Systems Analysis Guidelines*, pp. 36–44.
[11] Markuson et al., *Guidelines for Library Automation*, p. 31.

resources) that must be considered by the new system?

- What are the functions that must be performed by the system, in terms of:[12]
  —what triggers each function?
  —what are the restrictions on each function?
  —what are the data elements used in the function?
  —what processing steps must take place in the function?
  —what volume of processing per period of time?
  —what is the frequency of execution of the function?

How these requirements are ordered or expressed is somewhat arbitrary. Markuson suggests a more general, less technical outline.[13]

1. Statement of general requirements
2. Scope of operations to be included
3. Statement of functional requirements, such as:
   Data elements to be included
   Data access points
   Status requirements
4. Statement of human factors requirements
5. Volume to be handled:
   Daily flow
   File size
   File maintenance
6. Statement of management data requirements, such as:
   Analyses needed
   Output products required
7. Statement of desirable features (can include operations, analyses, output products, etc.)

The following is a sample list of requirements for a circulation system.[14]

1. General requirements
   - Improve control over materials in circulation
   - Improve management data reporting
   - Improve control of books and unbound serials
2. Circulation operations to be included
   - Charging and discharging
   - Overdue control
3. Functional requirements
   - Data elements must include brief title, brief author, complete call number (including copy), date due, and borrower identification
   - Data access points to charge file (books circulation) must include title, call numl and borrower
   - Charges and overdues must be identifiable c daily basis
   - The system must not depend on conversion the shelflist
4. Human factors requirements
   - Due to high turnover, the system must designed so that it can be handled by relativ untrained clerks
   - Equipment must not be noisy and must require redesign of circulation area
   - Output products should be legible and con nient to scan
5. Volume to be handled
   - Daily: 1,000 charges and discharges, 50 ov dues
   - File Size: 40,000 maximum for circulation f 5,000 maximum users
   - File maintenance: Outside of discharg corrections occur at a rate of 10 per week
6. Management data requirements
   - Daily tally of overdues and charges
   - Monthly and yearly summary of overdues a charges
   - Desirable but not mandatory: Monthly tall loan activity for every borrower and averag all borrowers
7. Desirable features
   - Handling of interlibrary loans and pertin activity summaries
   - Analysis of loans by broad class categories
   - Inclusion of temporary borrowers
   - Lists of items in circulation on a daily basis v weekly cumulation
   - Use of automatic charging device and perı nent borrower cards
   - Integration of system with agency pay account number
   - Handling of reserve requests

Systems Design—The Other End of the Bridge

The system requirements as just described are basis for the systems design specifications, wl describe the nature of the system to be implemer

[12] U.S., Civil Service Commission, Bureau of Training, ADP Management Training Center, "Management Introduction to Automated Data Bases," Washir D.C., n.d., p. A-5. (Mimeographed.)
[13] Markuson et al., *Guidelines for Library Automation*, p. 42.
[14] Ibid.

and how it is to operate. These are expressed in a design document that serves as "the blueprint and point of reference for all subsequent implementation work. It provides all the information necessary to solicit bids, if equipment or outside assistance is needed, and to develop work assignments for library or other 'internal' personnel . . . . It must contain all the information necessary for the initiation of computer program design and coding, e.g., flow charts, data formats, file design, and operational procedures."[15] This final document is the result of the systems design phase, which "is concerned with formulating various systems that meet some or all of the requirements developed during the analysis phase. It also includes the critical review of the postulated alternative systems, the recommendation of the 'best' system, and detailed design of the selected system."[16] The following list shows the steps of systems design.[17]

1. Formulate initial systems design
   - Develop flowchart or functional diagrams and tentative system specifications
   - Conceptualize and study alternative system approaches
   - Refine system specifications
   - Obtain approval of initial design
2. Establish hardware specifications
   - Identify processing and offline storage requirements
   - Identify input and output characteristics and requirements
   - Identify any needed modifications for library application
   - Identify essential components at various levels of system implementation
   - Investigate procurement of equipment
   - Estimate lead-time requirement for obtaining equipment
3. Establish software specifications
   - Identify computer programs required
   - Investigate general-purpose programs suitable for system use
   - Develop specifications for program language to be used
   - Develop program documentation requirements
   - Investigate capabilities of programming staff available to library
4. Analyze costs
   - Analyze present operational costs machines, material
   - Analyze projected costs of automa tional system — men, machines, mat
   - Compare costs at projected levels of
   - Analyze transition costs — acquisiti mated system and costs of maintena systems during system implementatio
   - Identify cost of conversion of essential
   - Identify costs of training existing preparation of manuals, code books,
5. Assess changes resulting from automati
   - Identify alteration of routines, provis services
   - Describe effect on present staff organi
   - Consider increased capability, chan costs, etc
   - Consider potential of phasing co system into proposed agency, local regional systems
6. Investigate management problems
   - Investigate problems of managing fut tion

     Contractor facility

     Use agency computer facility
   - Investigate amount of computer tim to library and schedule for services
7. Report on system investigation results
   - Prepare two reports: general report staff, institution management, etc report for further implementation ac
   - Prepare displays, charts, etc., cove points for staff and other briefing sess
   - Report on investigation to library as appropriate
   - Develop schedule for further impl plans
8. Perform project reporting and review
9. Obtain approval for further system in tion

The systems design phase should be creative phase of the automation process. firmly based on the system requiremen experience gained from the description of t system, but it can look beyond existing procedures, or operations. The system des done by a team consisting of a librarian processing experts. Working together, the

[15] Ibid., p. 56.
[16] Ibid., p. 43.
[17] Ibid., pp. 44–45.

onceptualize and study alternatives from both library nd data processing standpoints. The best system will eet both data processing needs and library needs ithout undue distortion of either.

It is during the system design phase that the bridge n be used. In the following section the characteristics minicomputers will be explored in terms of library pplications system requirements.

IBRARY APPLICATIONS

ENERAL

In the systems design phase a manual system may ppear to be the proper solution. Although almost nything can be automated to one degree or another, ot everything should be.[18] Manual activities, such as oving materials, shelving books, and opening packges are not suited for automation in a library, as they ight be in a warehouse. The intellectual activities of tting policies and making decisions can be supported automated statistical analyses, simulation, and odeling, but except for those simple decisions that n be reduced to algorithms, the decisions themselves nnot be automated. The same can be said for the ersonal services of a library. Automated products and erations can aid a reference librarian in the one-tone interaction with a user, but they cannot complete- replace the human element.

The clerical activities of the library are the best ndidates for automation. These are typified by cordmaking and keeping, data manipulation (such sorting or searching), and data control. Even in the erical areas, not everything should be automated. In any cases, the most efficient system is not one that does it all," but one that does the routine or standard sks while leaving the exceptions to be done by uman beings.[19]

If automation is appropriate, it can be accomplished a large-scale computer system, network, timearing service bureau, minicomputer system, or ombination of these. Some applications, some user eeds, and some sizes of libraries typically call for rtain types of systems, but the options should be left pen.

There is no one type of library or size of library that ould or should not automate. It was once axiomatic at no library with a collection of fewer than 100,000 ould automate, but Swihart and Hefley suggest that the minimum size for an independent system is 25,000 titles, which brings many more libraries into consideration.[20] Even that number is not inviolate. Sometimes the organizational structure of a library and the structure's complexity can dictate automation, as can the structure of the parent agency in which the library resides. Staffing problems can suggest automation as a solution. For example, either a hiring freeze that results in a lack of clerical support due to attrition or a one-professional shop that requires careful allotting of time can justify an automated system to absorb part of the housekeeping load.

Minicomputers themselves have opened up both more libraries and more library activities to automation. Minis are small, simple, and modular, and they can be used in smaller applications. Minis are ideally suited as single-purpose, dedicated systems. It is conceivable that several mini systems serving a library could be more economical than a single computer system trying to provide the same service. Using a system of several minis allows a library to introduce automation one module at a time. The separate modules could be connected but would remain basically independent. Minis, because they are so flexible and well suited to small-scale applications, can be used in connection with other automation systems as complements or supplements to such systems, or as components. Even libraries that already have automated systems could consider potential mini applications.

In looking at library applications, the major operational areas of the library (cataloging, circulation, serials, interlibrary loans, acquisitions, reference, SDI, and administration) will be used as points of reference. Keep in mind, however, the various approaches to automation reviewed in Chapter Two. Consider also that in any one library the various functions performed can be placed under a number of departments. For example, serials can be part of cataloging, part of acquisitions, or a separate unit. Interlibrary loans can be part of reference, part of circulation, or completely independent. It is for such reasons that the specific descriptions in this book are only illustrative and are not detailed models for imitation.

Markuson and her collaborators reviewed the major library areas and developed a series of lists of functions

---

[18] Ibid., p. 70, for additional discussion.

[19] Cox, Dews, and Dolby, *Computer and the Library*, p. 45.

[20] Stanley L. Swihart and Beryl F. Hefley, *Computer Systems in the Library: A Handbook for Managers and Designers* (Los Angeles: Melville Publishing Co., 1973), p. 10.

involved in the performance of the tasks of these areas.[21] These function lists illustrated that there are "recurring basic functions and tasks: record preparation, record input, filing, file maintenance, searching, materials handling, etc." This approach goes beyond looking at the area on a step-by-step basis as plotted in the flow chart and helps the design to be solution-oriented, rather than merely a replication of the existing system.

ACQUISITIONS

Markuson and her coworkers saw acquisitions systems as centered around two basic groups: (1) fund accounting activities that deal with the "management and control of fund allotments and expenditures and related functions," and (2) order control activities that entail "machine-readable input of order information and the generation of a variety of output products."[22] The Columbia University acquisitions project established "three levels of data flow, namely, (1) process control, or the flow of order data and the processing status of each order through the system; (2) fiscal data flow, or the encumbering of funds, paying of invoices, and reporting of fund status; and (3) bibliographic data flow, or the assembling, verifying, storing, and transferring of bibliographic data needed in the cataloging process..."[23] In either case, the following list of acquisitions functions and subfunctions is useful as a summary.[24]

1. Establishment and Surveillance of Policies and Procedures
   - Policy development
   - Maintenance of procedure manuals
   - User feedback analysis
   - Performance analysis
   - Establishment of procurement sources (vendor files, blanket order agreements, etc.)
   - Interlibrary cooperation
2. Fund Control
   - Allocation of fund allotments
   - Fund encumbering
   - Invoice clearing
   - Voucher preparation
3. Materials Selection
   - Review of, and selection from, notices of potential items
   - Approval of purchase requests
   - Identification of desiderata materials
4. Order Preparation and Control
   - Screening and distribution of purcha
   - Searching and completion of bibliogr data
   - Vendor and fund assignment
   - Order approval
   - Order form preparation and file monographs, serials, gifts and exch
5. Materials Handling
   - Material sorting and distribution
   - Routing
   - Control of items through processing
6. Receipt processing — monographs,
   - Item verification
   - Invoice verification
   - Claiming
7. File Input and Maintenance
   - Record input preparation and revision
   - Error correction
   - Transaction control: additions and del
   - Use of data from outside source
8. Output Generation, Dissemination a ing
   - Preparation of order forms, cancellat
   - Printing of lists of items on order
   - Output of change or control cards
   - Preparation of preliminary catalog cop
   - Preparation of accessions lists
   - Dissemination of order lists, dealer ca notices, etc.
   - Dissemination of products
9. Gifts, Exchanges, Memberships, V Other Sources
   - Control of gift sources
   - Control of exchange partners
   - Control of memberships
   - Control of vendor agreements
   - Maintenance of vendor and other sour
10. Reference and Retrieval
    - File searching
    - Retrieval of items in process
11. Processing Records from Outside So
    - Selection of records identified for purc

Modification of records for local use
Dissemination of hardcopy records
Analysis of subject coverage

The major activities of the *establishment and surveillance of policies and procedures* function are intellectual in nature. Automation in this area will generally be limited to support. Data from other automated areas (for example, the management information system) can be provided on which to make decisions; analyses can be performed by computer (for example, statistical procedures as part of the surveillance of the system); and procedures manuals can be updated by a text-editing computer system.

Fund control is a natural area for automation. Bookkeeping has been automated in business and industry for some time because this reduces redundant manual entries and improves accuracy. The information on each order or transaction must be kept current, manipulated many times, and used for a number of purposes. Done manually, this job often requires many files or at least many massages of the file. The capture and control of the order information is well suited to automation.

Materials selection is not even considered acquisitions in some libraries. However, the selection area is where the initial capture of the bibliographic elements occurs, so it does have an impact on acquisitions. This function also uses information from the acquisitions system: Is this book already in the collection? Is it already on order? Is it for sale from a regular source? Is there enough money to cover its cost? So, although the final selection probably will be a human decision, automated processes and files can support this function.

Order preparation and control is a mixture of clerical and intellectual activities; the extent to which it can be automated varies. For example, searching and completion of bibliographic order data could be automated if the *Books in Print* Data Base in machine-readable form were available, or if MARC tapes were available to search, or if a jobber's file, such as BRO-DART's IROS system, were available online. Without these data bases, this function could not be effectively automated. Vendor and fund assignment can be automated if the rules for the decisions can be

Materials handling is largely a manual ope
although automation could support such a func
routing. The control of the item through proce
where the automated system can best perfor
example, if a status code is carried in the rec
each item and updated as the item travels throu
flow, the item always can be located and retriev
do this manually requires many files and/or
refiling.

Receipt processing entails physically handling
als and making individual judgments based
original order information. Although human
ment is required, the data required to ma
judgment can be supplied by an automated p
Followup activities connected with claiming a
tied to the order subfunctions. This functio
provides information for other subfunctions s
fund control invoice verification.

The remaining functions on the list can be
ered as subfunctions of the other areas. They co
be automated as parts of other automated proc

The use of minicomputers as part of a new
should be determined by specific problems or n
the library. For this discussion, however, a num
typical problem areas in acquisitions can be liste

- Maintenance of the vendor source file
- Control of standing orders
- Control of a depository collection
- Control of items in process
- Preparation of orders and status control
- Bookkeeping and accounting
- An agency accounting system with wh interface
- Control of a processing center serving n units
- Integration of purchase request items s from MARC tapes
- Loss of service from the present large-scal system
- Control of preview and purchase of aud materials

All of these areas can be supported by a minico
system.

To illustrate the use of the design mod
bridge), one of these problem areas will be de
as a case study and "walked across" the bridge

Table 15—Acquisitions: Detailed Functions and Operations

Function & Description	Operations	Relationships	Files and Description	Inputs	Outputs
ESTABLISHMENT AND SURVEILLANCE OF POLICIES AND PROCEDURES					
Policy Development *Decisions as to selection criteria and procurement policies.*	Selection criteria is an intellectual effort based on professional judgment and organization objectives. Procurement decisions may have to be based on regulations imposed by the parent agency. (For example, policy may dictate using only jobbers, no jobbers, competitive-bid contractors; all purchase orders, no purchase orders, blanket purchase orders, standing orders, etc.).	Relates to parent organization. Input from User Feedback. Analysis as potential for policy changes. Input from Performance Analysis considered.	May involve a collection of manuals or regulations for the parent agency.		
Maintenance of Procedure Manuals *Details of how to carry out policy decisions, expressed as step-by-step procedures for staff.*	Each procedure must be expressed in writing, with appropriate forms and attached samples.	Covers the entire acquisitions flow. Will relate to other functions at specific points of interface.	Must be in a written form (duplicate copies desirable). Must be updated as necessary to keep current.		
User Feedback Analysis *Information from users on any phase of collection building or maintenance.*	Consideration of comments on what is purchased, time or speed of providing, availability, etc. Alterations in policy as required.	Can provide input to Policy Development.	May be solicited through a survey or may be spontaneous.		
Performance Analysis *Management information used in evaluating performance and forming decisions.*	Gathering of data; statistical treatment and analyses of data; interpretation of results for management.	Related to Control of Item Through Processing function, Claiming function, Vendor transaction file (or equivalent).	Specific files must be structured to record volume, time spans between events, etc. May be automatically kept or run through specific program (tally) and gathered on a periodic basis. Parameters required must be established in advance.		Variety of hardcopy reports, charts, and graphs.

Establishment of Procurement Sources *May involve formal contracts or internal rules for choice of vendor.*	Decision on which, if any, jobbers and for what types of materials. Decision on blanket purchase orders (with whom and how many). Decision on establishing deposit accounts. Decision on approval plans—profiles, etc. Determination of direct sources—publishers, societies, etc.—and special purchase requirements. Decision on standing orders—by title.	May be based on Policy Development decisions. Related to Maintenance of Vendor File function. Related to Vendor Assignment function. Related to Control of Vendor Agreements function.	May have a file of RFPs, bids, contracts, purchase orders, special agreements, etc. Status, length of agreements, dollar amounts may have to be monitored here.		Information to Vendor File Maintenance function.
Interlibrary Cooperation *Formal or informal arrangements may be made between libraries, i.e., exchange programs or consortium memberships.*	A formal consortium agreement or informal agreement on what subject areas of collection building or journal holdings to share may affect selections.	Related to Policy Development and Selection of Materials functions.			
FUND CONTROL					
Allocation of Fund Allotments *Budgeting and allotments by subaccounts.*	Maintenance of balances in each subaccount. Reconciliation of encumbered and paid amounts.	Direct connection to ledger (if a separate file). Accessed for balanced status by Order Approval function.	Budget file may be separate from ledger or combined.	Fiscal year budget amounts. Any budget transfer amounts from ledger (if a separate file).	
Fund Encumbering *Bookkeeping ledger operation to record each order and link to each fund.*	Maintenance of a bookkeeping ledger for accounting of financial status.	Direct connection to budget account (if a separate file). Amounts to encumber, funds involved, and order number/vendor number comes from the Order Approval function.	Ledger: Must be accessible by fund account number, order number, vendor number. Contains alphanumeric data, but no bibliographic data. Requires simple computation. Will be added to and changed constantly (three to four times per record).	From Order Approval function.	Hardcopy status reports on a periodic basis.
Invoice Clearing *Record of payment of each invoice against each order, reconciliation of differences.*		Amounts to pay come from the Invoice Verification function.		From Payment Control function and/or Invoice Verification function.	

Table 15—Acquisitions: Detailed Functions and Operations—Continued

Function & Description	Operations	Relationships	Files and Description	Inputs	Outputs
FUND CONTROL—Continued					
Invoice Clearing—Continued			Currency of prime importance (lag can't be more than one day). Status of totals required continuously. Must keep historical data (dead or complete), which also will be accessed.		
Payment Control *Authorization of payment by check or voucher.*	Performance of Invoice Clearing function by combining the Invoice Verification and Ledgering functions by order number.	Direct connection to Ledger. Related to Invoice Verification function. Must have access to the vendor file.	If a separate file, would contain order number, vendor number, invoice numbers, check or voucher number, date. Must be accessible by order number, vendor/invoice number, check number. Numeric, no bibliographic data. Little or no update or status check required. Must allow for bank statement reconciliation. Additions to file in batch mode acceptable.	Invoice Verification function input (invoice number and amount tied to order number).	Written check OR Hardcopy voucher OR Machine-readable approval to an agency system.
MATERIALS SELECTION					
Review of, and Selection from, Notices of Potential Items *Involves use of bibliographies, review tools, publishers catalogs, alerting tools (manually printed).* *Can be an SDI list prepared from a machine-readable file (such as a MARC tape)*	Available titles are reviewed often by a team of people representing various subject disciplines (can be by users outside the library). Some SDI systems prepare lists from a profile of the user, which is then re-	Direct connection to next step.		Can be from MARC tapes or BIP tapes. Can be part of BRODART IROS system or	

Preparation of Purchase Requests *An individual record for each title.*	All available bibliographic data identified for each title is captured, along with information as to source of request and priority (when needed).	If from a machine-readable tape or data base, this can be used to produce the record (hard-copy and file).	Manual (paper) file of individual records: ●bibliographic data ●selection source data ●order data if available OR Machine-readable file of the elements available from the source file: ●bibliographic data ●order data (e.g., price, ISBN)		An individual record for each title requested.
Approval of Purchase Requests *Each title is reviewed to determine whether to purchase or—for gifts and exchanges—to accept.*	A judgment (usually performed by a professional librarian) as to which titles to buy. Decision criteria are available, but algorithms are difficult to prepare.	Can be performed after the File Search function, which determines if title is a duplicate (local library option).	A sort of purchase requests into two files, one of selected titles and one of rejected titles. Rejected titles may be returned to selector for notification.		A group (or file) of records which goes to the Order Preparation function.
Identification of Desiderata Materials *Titles to be held on a "want" list.*	Titles that are not in print or available for purchase at request time are reviewed to determine if they should be purchased through a remainder dealer, out-of-print catalog, reprint list, or book exchange list. This is a costly procedure, so only selected titles are put on the "want list." Review of these special tools can be in Selection function or Order function.	This is the next step after Searching and Completion of Bibliographic Order Data for those titles determined not to be available. This also follows the Claiming function for titles reported as "out-of-print" or "not yet published." Goes back to Order function for review of status. Goes back to Order function when source is identified.	A file (list) of titles: ●bibliographic data ●order status ●search trail and history, i.e., catalogs checked and when.	Record of a title from the Order function.	Record back to the Order function when source is identified.

Table 15—Acquisitions: Detailed Functions and Operations—Continued

Function & Description		Operations	Relationships	Files and Description	Inputs
ORDER PREPARATION AND CONTROL					
Screening and Distribution of Purchase Requests *Sort by type (monograph or serial), foreign or domestic, etc., to determine who and how to search.*	Some libraries separate orders by type: monograph, serial, document, microform. Some libraries separate by foreign and domestic sources. Intellectual decisions that could possibly be machine-edited (algorithms) but would have to be human-reviewed.	Next step from Approval of Purchase Request function. Connects to next step.	Sort by categories (locally determined). No file as such. Determination of whether duplicate requests are present; if so, they are gathered.	Purchase request records (manual or machine-readable).	Purchase request records (sorted).
Searching and Completion of Bibliographic Order Data *Verifies and completes the author, title, edition, imprint information, adds data on ISBN, cost, etc.* *Determines if title is currently offered for sale.*	Current tools, such as BIP, PBIP, FC; publishers' catalogs; document lists such as MC, GRA, etc.; exchange lists; reprint lists; microform catalogs; out-of-print catalogs are used to complete and/or verify the titles desired. Some libraries require a list price; others order on an open price.	Related to decisions made in Establishment of Procurement Sources function.	If records were previously in a machine-readable file, the entire record is subject to changes and additions. BIP et al. searches are done by author or title; records should be so ordered. Publishers' catalogs are by vendor first, subsorted by author or title. Online files such as BRO-DART's IROS are accessed by author/title search key.	Purchase request records (sorted).	All titles not found to be available are sent to the Selection function for desiderata decision.
Vendor and Fund Assignment *Determines which fund or subaccount to charge the purchase to.* *Determines whom to purchase the title from if there is a choice.*	Parameters for decisions can be drawn up and algorithms used. Choice of jobber or direct purchase. Fund accounts can be internal to the library (general collection, reference, periodicals); can be charged to a program (PPBS) or objective (MBO); can be charged to a department or section of the agency or parent organization.	Related directly to Establishment of Procurement Sources function. Access to vendor file to establish special imprints, conglomerate relationships, and distributorships. Also special ordering restrictions, e.g., pro forma, minimum orders, purchase orders required, membership required.	Vendor code and fund account numbers are added to each record. All titles for same vendor should be brought together.		

Order Approval *After check of availability of funds and check for duplicates, the order is approved.*	Balance of each fund to be charged against must be checked for sufficiency, then encumbered against when order number is assigned. Order number assigned. Signatures given if required.	Can be performed after the File Search function that determines whether title is a duplicate, if not part of Selection process (local library option). Accesses fund balances and gives encumbrance information to Ledger.	If still in manual form, computer input should occur here. Records must be at the individual title level. Bibliographic data and order data. ●access by: author and/or title, order number, vendor number. ●serves as an on-order file, or is combined with an in-process file with "on-order" status code or is combined with main catalog file. Order file and/or vendor file of orders may be required: ●access by order number and vendor number ●must carry details of each title on order ●will be accessed for individual status on a title and order level ●updates on status will occur at any time ●currency is important ●entire fiscal year history must be maintained.	Balance information for each fund involved.	(Data transfer) Amounts to be encumbered for each fund (includes order number, vendor number). Some require printouts of on-order list. Some use prepunched cards for book on order or journals due in Receipt Processing function. Orders printed ready for mail.
Order Form Preparation and File Control	Preparation of individual orders ready for mailing.	Related to Receipt Processing function. Pre-cataloging may occur (local library option).			
MATERIALS HANDLING					
Material Sorting and Distribution *Separation of incoming materials from all sources by destination.*	Manual. Sorting of incoming mail, packages, shipments. Routing to specific check-in points. Ex.: monographs are generally checked in separately from periodicals.	Will connect to Receipt Processing function.	No specific file created. Materials can be stamped with arrival date.	Comes from U.S. mail, parcel delivery, truckers.	
Routing *Generally dealing with newspapers and periodicals that are sent directly to users according to a predetermined list by title.*	When a routing list is established in advance by journal title, the list is matched to the copy, affixed, and sent off. Comes after issue has been formally checked in.	Related to and comes from Receipt Processing function.	Profile of users (or departments) that are to receive each title, often in a priority sequence. Must change with change in personnel.	Preprinted lists of names on routing list by title.	

Table 15—Acquisitions: Detailed Functions and Operations—Continued

Function & Description	Operations	Relationships	Files and Description	Inputs	Outputs
MATERIALS HANDLING—Continued					
Control of Item Through Processing *Must be able to locate a specific title, if needed anywhere along the processing flow.*	Each title must carry an active status to show where it is in the processing flow. This will change as it goes through each step. Can be a series of files or a master file with status updated. Includes binder control and routing control for periodicals. Ends when material is on shelf and represented in catalog ready for public use.	Related to Order File, Item Receipt function, Cataloging section, Processing section, and Circulation section. Related to Performance Analysis function. Related to Retrieval of Items in Process function.	File of individual title records with full bibliographic data and some order information. ●must access by author, title, order number ●must search and list by status: all books on order; all books received, not cataloged; all books cataloged, not labeled; all books labeled with no circulation control data ●searches may have parameters applied.	May be actual paper cards/work slips to indicate status. Ex.: prepunched card sent forward on arrival of title. May be output of other functions.	Potential hardcopy lists on demand and/or periodically.
Routing continued	Analyses may be required. ●statistical counts ●time flow plots.		May be separate files by function. May be part of main catalog. Will be a large, active single file, often accessed, often updated and changed. Currency is important. Input must be as efficient as possible due to great volume.		
RECEIPT PROCESSING					
Item Verification *Checking and verification of each item received against its order or list. Checking also for damage.*	Materials come from a single source (e.g., vendor) and may be unique to a single order number. Each title is examined against bibliographic data of order to verify correct title, edition, etc. If correct, title is flagged as received. This updates in-process status and eliminates duplicate shipments from	Must have access to order, subscription, exchange list, etc., on which item was initiated. Must update order status in Order file (vendor transaction file). Can be performed concurrently with Invoice Verification (next step). May require Claiming function.	If a vendor transaction file, the order number and specific titles must be accessed and updated. Must determine if order is complete or not. If an order file, the specific title must be updated—order may or may not be complete. If an on-order file by item, the title must be accessed and status flagged. May be considered closed or	Material comes from Materials Handling function.	

	procedure will be required.		by item, the title must be updated to change status.		
Invoice Verification *Checking of each amount and item on an invoice to lead to approval for payment.*	Must verify receipt of proper item with no outstanding claim. Must verify that charge matches item (both paper, both same number of copies, etc.). Must verify not prepaid. Must verify proper discounts applied if eligible.	Must be closely tied to Item Verification function. Related to Fund Control "Invoice Clearing" function.	Establishes exact cost of each item purchased, which must be recorded, as well as miscellaneous charges such as postage, handling, and tax. If order file is not updated here (by title), it must be updated in Invoice Clearing function (best here because a "by-item" approach is more efficient here).	Invoices may come separately by mail; must be held for matching. May require credit memo to match against invoice.	
Claiming *To resolve order problems such as no item received, wrong item received, damaged item received, incorrect invoice, no invoice received, partial receipt of order.*	Requires correspondence (or telephoning) with vendor. May require vendor's permission to return before shipping. Requires control of pending condition for an item, invoice, and order.	Connected to Item Verification and Control of Item Through Processing or On-Order File function. Must access Vendor File.	Must have complete order, vendor, bibliographic, and status information. Must have a pending/follow-up capability for each claim; access by vendor number, order number, item (author/title), date, category of claim. May not be separate, but rather recorded as a status or condition in another file(s).	Some vendors provide claim forms to use, including blank credit memos for use as needed.	Letters or forms to vendor: ●permission to return ●request for missing invoice ●request for status of a title and/or an order ●request for credit memo ●request for missing copies. Mailing labels.
GIFT, EXCHANGE, MEMBERSHIP, VENDORS, AND OTHER SOURCES					
Control of Gift Sources *Includes philosophy and mechanics of gift procedure.*	Must consult gift policy as to kinds of gifts, dollar amounts, numbers, and conditions or "strings" attached. Must determine if a tax form will be provided.	Related to Materials Selection function. Related to Fund Control function to record dollar value for reports and insurance.	Must maintain name and address of donor; number, type, and dollar amount of gifts accepted or rejected; may require a list by title.		
Control of Exchange Partners *May be a membership in a cooperative or on an individual basis.*	May be a membership in the U.S. Book Exchange or individual arrangements. May involve payments. May involve review of lists or receipt of boxes. May involve creation of lists.	Many, but will vary with nature of agreements.	Must maintain: bibliographic information ●on titles offered ●on titles considered ●on titles selected financial data ●on titles sent off ●on titles selected transaction data on each shipment for control.		

Table 15—Acquisitions: Detailed Functions and Operations—Continued

Function & Description	Operations	Relationships	Files and Description	Inputs	Outputs
GIFT, EXCHANGE, MEMBERSHIP, VENDORS, AND OTHER SOURCES—Continued					
Control of Memberships *May be library-initiated or agency-initiated.*	Some fees are charged to a special fund (either library or agency). Some memberships are required to purchase materials. Some memberships provide free materials automatically.	Related to: Fund Control Vendor Assignment Vendor File Materials Selection Control of Item in Process Retrieval of Items in Process etc.	Must have organization data (name, address, cost of fee, length of membership); must access by name and time of expiration. Must have profile of services: ●purchase arrangements, e.g., discounts ●free titles, automatic or by request.		
Control of Vendor Agreements	Details of each agreement must be kept as to nature, requirements, profiles, dollar levels, length of agreement. Types: Blanket purchase order –one vendor, dollar ceiling. Approval plan – frequency of review, profile, shipments, returns, payments, discounts. Deposit Accounts – one vendor, dollar ceiling. Jobber Contract – level of commitment, length of contract, may have dollar minimum, discount may vary on volume. Standing Orders – by title in a vendor/frequency sequence.	Many, but will vary with nature of agreements Related to Establishment of Procurement Sources function.	Agreements with dollar levels must be encumbered, paid against, and reconciled with each transaction. This status must be accessed in the Order Approval function. May be part of regular order control flow, with access and reporting available as above.		Reports—periodic or on request—on levels and status.

Maintenance of Vendor and Other Source Files	Control of a master file of information on each vendor, jobber, society, etc. (procurement source) that is an actual or potential source. Reflects the relationship of the book trade industry; profiles of each vendor; specific arrangements with individual library.	Accessed by: Payment Control function Vendor and Fund Assignment function Order Form Preparation function Claiming.	File of Vendors' Information: Control number Name, address, phone number, order-to address, claim-to address, ship-(return) to address Specifications: ●must have purchase order number ●must be prepaid ●must have minimum dollar amount per order ●must have minimum number of items per order ●must have membership ●approval plans available ●standing orders ●deposit accounts. Control over minor presses, imprints, publishing houses, distributorships (cross-references).

Case Study

Problem Area

An efficient means of handling cooperative acquisitions among branch libraries is needed.

Library Environment

A Federal agency has 14 branch or field libraries throughout the United States, as well as a main library at the headquarters in Washington, D.C. A central processing unit provides technical services for all of the libraries. Each library performs its own book selection, and the processing unit orders what is requested. About 4,000 volumes are acquired each year.

Goals

It is desired to coordinate the selection, acquisitions, and cataloging processes of the 15 libraries and the processing unit.[25] The intended benefits will be:

1. Professional expertise used in the book selection process will be shared among the libraries. Clerical efforts will be reduced by elimination of redundant searching, typing, and verification.
2. Collections will be better balanced. Expensive items may not be duplicated within the system and an interlibrary loan will be used if a book available at one branch is needed at another.
3. There is the possibility of earning a volume discount on purchases of multiple copies of a single title.
4. Cataloging will be more efficient if it deals with multiple copies of a single title at one time, rather than performing the added copy routine a number of times.

Proposed Flow

A library will research and select a title to add to the collection through the regular selection workflow (see the Materials Selection function). The bibliographic elements of the purchase request will be keyed, i.e., entered into machine-readable form. On a biweekly schedule, the purchase requests will be sent to the processing unit. The purchase requests from all the libraries will be merged and sorted (see the Order Preparation and Control function). A combined list will be sent to each library. The list will be reviewed by each library and additional copies desired will be indicated. The lists will be returned to the processing unit. The purchase requests will be me
by vendor, and the orders will be prepa

TABLE 17—Alternative 1

Design Characteristics	Hardware/Software Impacts	Library System Specifications
Means of Inputting One-way.	I/O Device: input only. Ex.: keyboard, card reader, paper tape reader.	Keypunch machine at each library. Punch card reader for computer configuration.
Types of Output Products Hardcopy: Special forms and multiple copies.	I/O Device: printer with special paper capabilities–probably an impact type to handle multiple copies.	Impact printer, probably a line printer for speed in printing 15 copies (i.e., three or four runs).
File Structure and Size Structure: Sequential.	Mass Storage Device: any type can handle sequential. Ex.: punch cards, paper tape, cassette tape, magnetic tape, diskette, or disk.	Open (Class III dictates no disk).
Applications Characteristics Sorting: Alphabetic.	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.	Optional (Class III dictates magnetic tape or diskette (if capacity is large enough).

TABLE 18—Alternative 2

Design Characteristics	Hardware/Software Impacts	Library System Specifications
Means of Inputting One-way. Outside source: Offline machine-readable form.	I/O Device: key-to-disk station or intelligent terminal. System Software: floppy disk operating system.	Key-to-disk station at each library. Floppy disk drive for computer configuration.
Type of Output Products Hardcopy: Special forms.	I/O Device: printer with special forms capability	Printer, line or character.
Machine-readable output form (offline).	I/O Device: same medium as input station, i.e., floppy disk. System Software: floppy disk operating system.	
File Structure and Size Structure: Can be either sequential or direct access.	Mass Storage Device: any type can handle. Ex.: cassette tape, magnetic tape, diskette, or disk. Size of file is the controlling variable.	Open (Class III dictates no disk).
Applications Characteristics Sorting: Alphabetic.	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.	Optional (Class III dictates magnetic tape or diskette if capacity is sufficient).

Design Characteristics	Hardware/Software Impacts	Library System Specifications	Minin Class Comp
Means of Inputting			
Conversational.	I/O Device: two-way (output or response capability).		
Location of input stations.	Communications Equipment: hardwire or telecommunication line.	Due to distances of the libraries, telecommunications lines and equipment must be used.	IV
Multiple online users.	I/O Device: two-way (conversational capability). Communications Equipment: telecommunications lines or hardware lines. System Software: must handle telecommunications functions if that method is used.	Terminal must have modem.	
Type of Output Products			
Hardcopy: Special forms	I/O Device: printer with special forms capability.	Printer, line or character.	
File Structure and Size			
Structure: Direct access	Mass Storage Device: disk device (diskette, fixed-head disk or movable-head disk). System Software: disk operating system.	Disk system.	
Application Characteristics			
Sorting: Alphabetic	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.		
Remote Access	Communications Equipment: hardwire lines or telecommunications lines and modem. Communications Controller: may require a processor.	Telecommunications system.	

TABLE 31—Typical U.S. End User Printer Equipment Prices and Speeds

					Comments
Impact Character					Multiple copies possible,
(Shaped Character)					preprinted forms possible
Speed (characters/second)			10–30	60–120	
Price ($000)			1–4	4–6	
Impact Character					Multiple copies possible,
(Dot Matrix Character)					preprinted forms possible
Speed (characters/second)			30–100	115–660	
Price ($000)			2–8	4–12	
Impact Line					Multiple copies possible,
(Shaped Character)					preprinted forms possible
Speed (lines/minute)	90–250	300–700	800–1800	2000	
Price ($000)	3–17	3–51	35–80	74–112	
Non-Impact Character					Requires special paper,
(Dot Matrix Character)					single copy only
Speed (characters/second)			10–240		
Price ($000)			1–4		
Non-Impact Line					Requires special paper,
(Dot Matrix Character)					single copy only
Speed (lines/minute)		300–600	1000–3600	4000–18,000	
Price ($000)		5–10	7–13	165–310	

Teletypelike Terminals. Teletypelike terminals have keyboards for input; they print on paper for output. Some character printers with keyboards included could qualify as input/output terminals. Many of the same characteristics of the printer apply to these "teleprinters" (impact and nonimpact printing, speeds from 10 to 120 characters per second, upper case and upper/lower case, 80 characters per line or less and up to 132 characters per line). Table 32 gives price ranges for various types of Teletypelike terminals.

TABLE 32—Typical Teletypelike Terminals

Line Width	Print Speed	Price
80 characters per line or less	Up to 30 characters per second	$1,500–$5,000
More than 80 characters per line	Up to 30 characters per second	$2,000–$5,000
Generally 80 or more characters per line	Up to 120 characters per second	$2,300–$5,500

Keyboard/Display Terminals. The most common keyboard/display terminals use a CRT for display. Although these have some characteristics in common with hardcopy printers, other characteristics are peculiar to display units.

Character format (size of the dot matrix used to form the characters) — Common patterns are 5 by 7 or 5 by 9 (the more dots, the more legible).

Display characters (total number displayed on the screen) — Usually 640–2000 characters.

Format (number of characters per line and number of lines per screen; the product of the two equals the total number of display characters) — Common formats are 80 characters by 12–24 lines.

Speed — The speed is equal to the transmission rate because there is no slowdown due to mechanical devices. If the CRT is connected as a TTY replacement, the controller will transmit the data one character at a time, with a speed that varies with the keyboard operator. The printer will work at a rate comparable to that of a Teletype. The more sophisticated controllers allow transmission in blocks at communications speeds, e.g., 9600 BAUD.

Character set — Upper case (64) or upper/lower case (96), a few with special characters capability (128).

Special features — Buffered or unbuffered; page mode; forms fill-in formats; function keys; line and character edit capability; double width characters; controllable cursor; reverse video; blinking; built-in modem; acoustic coupler; portable; and color.

Prices vary according to the combinations of features and elements. The bottom level is around $1,000,

d the top is more than $12,000. The top end has tures that place it in the intelligent terminal class. Some CRT controllers handle multiple units as a ster. Some units have the capacity to plug in a nter for hardcopy output.

›ftware

In many cases, systems software and an operating tem are included with the purchase of a minicomter processor. "Extras," in the form of utilities, npilers, and communications packages, are sold arately. Some manufacturers offer applications tware packages designed for special purposes. Many npanies will not sell these packages, but only lease m, to protect the proprietary nature of the packag-. This arrangement usually allows the user to receive latest, most up-to-date version of the software.

The following prices are offered from main mini nufacturers' business systems lists. They would not cessarily reflect prices from a systems house.

stems Software	
Jtilities	$ 15/month rental
Communications	$700 purchase
Operating system	$ 15/month rental
Compiler	$ 25/month rental
	$ 20 to $ 90/month rental
	$ 11 to $115/month maintenance

plications Software	
Purchase	$ 500 to $3500
	$ 600 to $ 750 plus $12.50/month maintenance
Lease fee	$ 175
	$ 250 to $1450 plus $10 to $65/month
	$2500 to $4600
Monthly rental	$ 75 to $ 420/month

ystems

Many of the major minicomputer manufacturers er entire systems. Such a system includes a complete rdware configuration, a software package, and netimes even application packages. The system is ered at a price that is less than that of a piece-by-ce purchase. This is particularly true for intelligent minals, which often have all the components in a gle cabinet. Some systems are for general applicans, but some are configured for special purposes. For ample, Raytheon has a system especially designed distributed processing. Digital Equipment Corp. s a word processing system in the Datasystem 300 series; and Burroughs has an entire series of systems for work-station based data entry/inquiry.

One type of system — the small business computer — has received much attention and has been widely developed by the industry. These systems are "generally characterized by purchase prices between $5,000 and $100,000 and by a strong orientation, in both equipment and software, toward conventional business data processing application."[23] They are developed by the main minicomputer manufacturers or by independent system houses or turnkey vendors. This market was assessed at $1 billion in 1976, and so has received a great deal of attention from the trade press. Articles that survey and review small business systems appear routinely, and looseleaf services such as Auerbach's *Buyer's Guide to Business Minicomputer Systems*[24] offer current information on the market.

One must be very careful in studying systems as described in the press. Not every vendor "bundles" his system the same way and not every reviewer presents the data the same way. For example, the *Datamation*[25] survey described the Datapoint Model 2200 one way, and *Mini-Micro Systems*[26] described it quite another:

Datamation	Mini-Micro Systems
Model Highlights No. installed/date: 9000 since April 1972 Multiprogramming: No Communications: 8 lines Applications: banking, insurance, government, accounting	*CPU* Word length: 8 Memory capacity: 4–16K *Data Entry Terminal* Video *Card Reader* 80 column (300 cpm)
Processor (Datapoint) Internal storage: 4K to 16K MOS (3.2 µsec) Word size/add time: 8 bits/4.8 µsec	*Disk* Capacity: 0.256–40M bytes *Mag Tape* Cartridges (2 units) Reel
Mass Storage Disks: floppy, cartridge, pack Access methods: random sequential, indexed sequential Magnetic tapes: reel-to-reel, cassette	*Printer* Serial 132 columns 30/330 cps Serial 120 columns 120/240 cps Line 132 columns 300/600 cps
Peripherals 10-key, card, serial printer (120 cps), line printer (to 600 lpm)	*Communications* Asynchronous and synchronous

3 Steve A. Bobick, Edmund J. Armon, and Arthur W. Yerkes, "Survey of Small Business Computers," *Datamation* 22 (October 1976): 91.
4 *Auerbach Buyers' Guide to.* For information on minicomputers for libraries, see *Advanced Technology/Libraries,* 1972-
5 Bobick, Armon, and Yerkes, "Survey of Small Business Computers," p. 96.
6 Malcolm L. Stiefel, ed., "Small Business Computers," *Mini-Micro Systems* 9 (July 1976): 52.

Software
RPG BASIC, assembler, DATABUS, SCRIBE, DATA FORM, DATA-SHARE, accounting package, DBMS

Basic Prices
$8,571 ($216/mo., 2-yr.)
Software and support extra

Programming Languages
DATABUS, BASIC, RPG II, assembler

Modes of Operation
Online batch

Typical Prices

Purchase	$45,000
Monthly rental	$1,200
Maintenance	$250

How does one compare these data? The *Datamation* price is for a basic system (probably the processor only, with the lower end of the memory). The cost of mass storage devices, peripherals, and data communications equipment would be extra, as would the cost of software. The *Mini-Micro Systems* price includes more and is more representative of what this system would actually cost.

An interesting comparison can be made between two entries in the *Datamation* survey:[27]

	Applied Data Communications	Datapoint
Model Highlights	*Model 101*	*1100 Series*
No. installed/date	Introduced in August 1976	6,000 since January 1974
Multiprogramming	No	No
Communications	One line (bisynch 2780, 3780)	One line (2265, 2741 2780, HASP)
Applications	Manufacturing, inventory, food processing	Banking, insurance, government, accounting
Processor	Datapoint 1100	Datapoint
Internal Storage	32K MOS (1.6 μsec)	16K MOS (3.2 μsec)
Word size/ add time	8 bits, 16 μsec (5 digits)	8 bits, 4.8 μsec add time
Mass Storage		
Disks	Floppy	Floppy
Access methods	Random, sequential indexed sequential	Random, sequential indexed sequential
Mag tapes	Cassette	Reel-reel
Peripherals	10-key, serial print (to 165 cps), line print (300 lpm) crt	10-key, card serial print (120 cps), line print (to 600 lpm) crt
Software	BASIC, assembler, Data bus II, accounting package	RPG, BASIC, assembler, DATABUS, SCRIBE, DATAFORM DATASHARE, accounting package, dbms
Basic Prices	$29,990 ($690/month) soft and support included	$7,200–$12,900 ($165–$214/month) soft and support extra

The differences here stem from what is included in the basic system. For the minicomputer manufacturer Datapoint the basic price is for the processor and only a few peripherals. No software is included. For the systems house vendor Applied Data Communications the basic system is more inclusive and includes the software. Again, careful comparisons must be made.

EVALUATION

In preparation of an RFP, the criteria to be used in reviewing the proposal are drawn up and often are included in the RFP. The criteria should cover not only the hardware and software, but also the manufacturer and/or vendor's track record, the previous experience of the system (or hardware), and the responsibilities for maintenance of the system. The University of Chicago suggested that the following points be covered as the basis for review.[28]

1. Reputation of manufacturer/supplier — This criterion is the most subjective, but in terms of our requirements, is the most important. The hardware must be widely available and supported over the life of the system, which suggests the importance of dealing with an established vendor. The product must be currently demonstrable and of proven reliability.
2. Maintenance — Maintenance support must be available locally and should be of proven reliability.
3. Communications hardware architecture — The major task of the minicomputer system is that of driving approximately forty-eight lines with various transmission characteristics. The communications hardware must be capable of handling a variety of device types and communications characteristics and of processing the anticipated load, and have sufficient reserve power for expansion. Careful attention must be paid to whether the communications hardware controls transmission on a character-by-character basis (programmed I/O) or on a message basis (direct memory access).
4. Communications software support — In conjunction with the communications hardware, an extremely desirable feature is the availability of communications software.
5. Peripheral devices — Because the front-end computer system provides backup when the main computer is down, a heavy burden is placed on the peripheral devices, most notably on the disk drives which hold several processing files. The mechanical components of the system have the least reliability. Therefore, the disk and tape drives proposed must be devices previously installed and of high reliability.
6. CPU architecture — The state of the art in processor design has reached a point that many fast, reliable minicomputers are on the market. Therefore, CPU to CPU comparisons should be minimized as much as possible.

The points are often weighted as to relative importance. (See L.C. weighting schedule in Appendix B.)

Within each category further evaluation is necessary. Various schemes have been described in the literature. Many of these schemes are based on lists of pertinent factors weighted according to their relative importance to the application. Formulas are applied to compare the results of each proposal's weighted scores.

At an American Institute of Industrial Engineers (AIIE) conference on minicomputers, John Hughes suggested use of a vendor decision matrix.[29] The criteria he suggested were:[1]

1. Processor Architecture
   Word length
   Memory path width
   Interleaving ability
   Number of channels
   I/O channel data rate
   CPU cycle time
   Memory cycle time
   Number of registers
   Instruction set
   Main memory capacity
   Main memory type
2. Software
   Operating systems
   Data base/file management systems
   High level compiler
   Debugging aids
   Application packages
   Utility programs
   Communications handler
   Multiprogramming
   Editing
   Overlays
3. Maintenance
   Equipment Reliability: MTTF and MTTR
   Onsite FE [field engineer]
   Expense
   Spare parts
   Diagnostics
   Organization
   Preventative maintenance
   Contracts available
4. Marketing Support
   System documentation
   Programming manuals
   Custom programming
   SE support [system engineer]
   Training
5. Company Viability
   Time in business
   Profit picture
   Research and development
   Installed base
   User groups
   Future plans
6. Costs
   Purchase price
   Discount structure
   Lease basis

Once the criteria are established, the weights should be determined. Of the factors listed, some may be of no importance to the application; give them weights of zero. Those factors most important to the application should be given the top weight. The most common scale used is zero to ten. The weighting decisions can be aided by reviewing the hardware and software impacts discerned through use of the Design Model (Chapter Four). Auerbach reviewed the elements of hardware and described how each affects a system.[30] For example, if there is frequent data exchange between the CPU and the external environment (i.e., the peripheral devices), the interrupt efficiency is important and the machine chosen must process interrupts quickly and offer multilevel priorities.

Ollivier did more than subjectively assign weights at review time.[31] He broke down each factor in terms of possible responses and the value each should be assigned. This value is then multiplied by the weight. Table 33 shows an example. Although this appears to be a more scientific approach, a caution must be noted. Manufacturers use their own techniques to achieve the same purpose, and the factors are diffic··· to quantify precisely. For example, how wou'

TABLE 33—Weighting Scheme for Hardware ation

Factor	Weight	Scoring Bases
Word size	10	4: 16 bits or more; 2: 12 bits; 0: 8 bits or less
Cycle time	6	4: 1 μs; 3–1: 1–2 μs; 0: 2 μs
Instruction set	5	4,3: Extensive; 2: Adequate; 1–0: Primitive
Addressing	4	4–0: Score one for each of the following: indirect, relative, indexed, direct to greater than 4096, or by addressing
Interrupts	7	4: 3 or more priority, no identification necessary; 3–1: adequate for 3 devices; 0: none quoted
Physical size	1	4–0: Subtract one point for each 5 inches over 11 inches

rough's variable-word-size devices be compared with machines that use 8-bit, 16-bit, 24-bit, or 64-bit words? Barden suggests that the best way to overcome this problem in the area of speeds is by preparing and running benchmark programs for the various types of minicomputers.[32] The sets of benchmarks can vary according to the application. He illustrated benchmark programs run by the industry: I transfers 100 bytes of data from one block of memory to another; II converts a 6-digit ASCII octal value to a binary value of 16 bits; and III searches an 80-item string of characters for a given character. Table 34 illustrates the use of these benchmarks.

TABLE 34—Instruction Speed Benchmarks

Computer	Benchmark* I	II	III	Average
8008–1 μp chip	69,215	1,767.5	5,542.5	25,762
8080 μp chip	7,854	1,018	3,546	4,139

Nova 800	688	58.8	252.6	334
CAI LSI-3/05 (core)	4,006	339	1,248.75	1,865
Interdata 6/16	290.5	88.3	390.5	256

*Time in microseconds.

A similar approach would be to use an existing industrywide comparison. A classic study was done by Butler in 1970;[33] the data are obsolete now, but the approach is still viable. He used data for 45 models as a basis for a price-to-performance ratio by using three equations for calculating: the hardware price/ performance; the software price/performance; and the overall price/performance. He showed ratings for the 45 models based on overall price/performance values.

Some evaluation techniques stop when the weighting or weighting times value has been completed. This number can be said to provide a measure of comparison among various manufacturers.[34] The vendor with the most accumulated points is chosen for final evaluation. Ollivier suggests that some factors may be so critical to the system that their absence (a zero value or score) will eliminate the vendor from consideration no matter how high the system's total score was.[35] For example, if delivery is required in 45 days and the proposal offered 90-day delivery, the proposal would be worthless for this application.

Ollivier does not stop with the composite score. He advocates plotting cost against performance, using a minimum performance score and a maximum allowable cost figure as bases of comparison (Fig. 19).[36] In the figure it is obvious that system E is the best value, with system A in second place.

Turnkey Systems

If a packaged or turnkey system is included as one of the proposals (or if all of the proposals are for packaged systems), how is it evaluated? Delanoy, writing on the use of library minicomputer turnkey systems, advised the following.[37]

> In considering a minicomputer. . ., the most important characteristics are that the machine is part of an established and growing product line; the machine as configured is suitable and adequate for your application; the manufacturer-supplied software meets your needs; and the manufacturer's installation and maintenance commitments are clearly specified.

Weisbrod also wrote of library packaged systems. He said four major questions must be answered.[38]

1. Do the functions included satisfy the needs of the prospective user?
2. Can the system be configured to handle the prospective user's processing load?
3. What equipment is required, either for purchase or for rental?
4. What is the system's cost?

He pointed out that these are the same questions that must be answered for a system developed in-house. Therefore, in evaluating a packaged system one uses the same procedures as for any other proposal, but with more emphasis on the software.

"Software, not hardware, is the pivotal element in system selection."[39] That is because the real power and effectiveness of any system rests on its software. For a system purchased for in-house applications program-

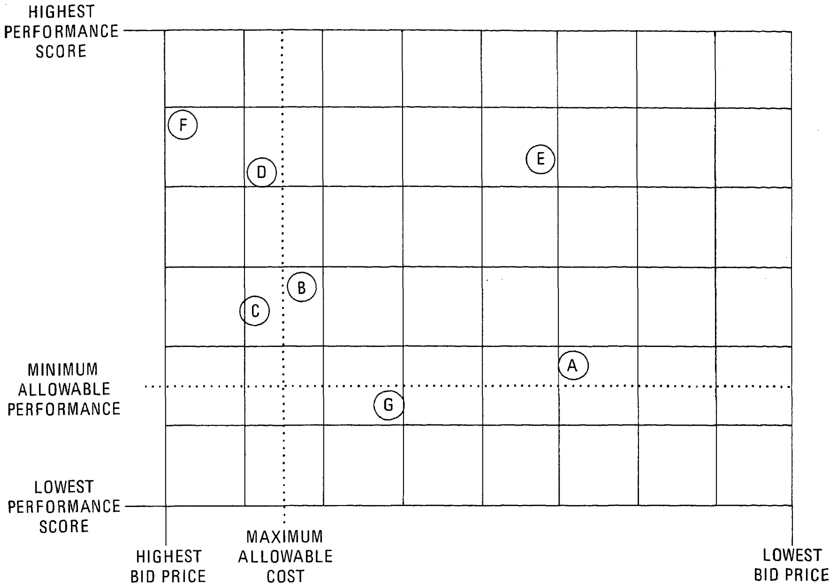

FIGURE 19. Cost versus performance evaluation grid

ming, the systems support software is of critical importance. It affects the development time and the efficiency with which the programmer can work. For a packaged system, the emphasis must be on the applications programs provided.

Stiefel states that two problems are shared by all software packages in the world.[40]

> First, it is highly probable that a given package won't precisely fit 100 percent of the requirements of a given business. After discovering the deficiencies, the . . . user either can correct them (i.e., bring in a consultant) or live with them. The extent to which a user can afford to compromise is a function of the seriousness of the discrepancies.
>
> * * * * *
>
> Ideally, the software should have the flexibility to be altered by the user, perhaps by changing parameter tables, to operate in a given environment, without causing a major upset in the using organization. Unfortunately, most packages have limited flexibility; some have none.
>
> The second problem with the precooked software approach is its lack of operating efficiency, measured in terms of usage of system resources (disks, core memory) and running time. Generality is *always* achieved at the expense of efficiency. Running time optimization isn't important in many small business applications where input is entered so slowly and so infrequently that virtually any reasonable response time will be acceptable. But the problem is, if resources are used inefficiently, the user may be forced into acquiring a larger configuration than he really needs, just so he can use a certain package.

Some vendors offer the service of preparing custom modules or customizing existing programs. Others do not which means the library must try to make the changes with their own and/or agency personnel, or they have to hire consultants. It is inadvisable to attempt some changes. Depending on how the programs are designed, some changes can be taken care of without much trouble. But some changes would jeopardize the basic logic stream and continuity of the program. These kinds of changes should be avoided at

[40] Ibid., pp. 56–57.

all costs because the number of changes in a program is inversely proportional to the success (efficiency and effectiveness) of the program.

REVIEW OF OTHER RESOURCES/REQUIREMENTS

Besides the obvious hardware and software requirements for a system, other types of requirements or resources must be considered. The details of these elements may affect the final selections.

Physical Requirements

Space

The site for the various pieces of equipment must be considered. Minis do not have to have a special room with raised floors and special air-conditioning and humidity control. Because they are small, they can usually be fitted into the existing environment without much trouble. If rearrangement of furniture or remodeling is necessary for the new equipment or for a new work flow, it should be established early and plans made to make the changes. In this same vein, if the equipment is to be placed in more than one location, provision must be made for laying cables or lines to connect the components (if a hardwire connection is used). Holes in ceilings or walls or channels for the floor may be required.

Although minicomputer equipment can operate under standard air-conditioning, some devices generate more heat than others, and adjustments may have to be made. Specifically, disk packs create quite a bit of heat; if they are used in multiple arrangements, the heat increase may be significant.

Power

Most minis operate on regular 110-volt electrical power. It is often recommended, however, that each device or each system power supply be on a separate line, often with a separate circuit breaker, to lessen the chance of surges. That doesn't mean one line per component, as many devices can be connected to a single power supply unit, but two or three lines are not uncommon. Special electrical rewiring may have to be completed before the system can be installed. Plans for this work should be made as soon as the exact locations and equipment requirements are determined.

Noise

While noise is not a "physical requirement," it is certainly a fact of life and must be considered, not only in the public service area but also in the staff work areas. The mainframe is not very noisy. The most disruptive noise comes from the fans used for cooling the processing unit. In addition, some disk drives whine and some tape drives click as the file is read. This noise should be within the tolerance levels for an office environment. The main noise comes from peripherals such as card punches, printers, and even hardcopy interactive terminals. Some libraries have taken special steps to deal with the problem of noise, as detailed by the editors of *Online* in their discussion of interactive terminals.[41]

> Some libraries go to great lengths to avoid noise. The Congressional Research Service of the Library of Congress, for example, built a special sound-insulated booth for its CRT and high speed impact printer. The U.S. Department of State's library simply put its Centronics printer in a closet and got a long cord to go to the CRT. And the Army Library in the Pentagon put a plastic noise-suppressing cover over its impact printer.

Maintenance

Although maintenance was mentioned in the discussion of hardware and software evaluation, additional comments are in order. In general, minicomputers are very reliable pieces of equipment.[42] Mean time to failure for minis is measured in months instead of hours. Preventive maintenance is reduced to the barest of minimums for the mainframe. The peripherals do not have quite so good a record. For instance, printers, especially impact printers, often require adjustments to provide proper print alinement. Tape drives should be cleaned periodically, but that is often done with a bottle of alcohol and a cotton swab.

The fact that maintenance is not as frequent for minis does not lessen its importance. The history of the mini market has been one of insufficient support after installation. One wit said that minis weren't delivered — they were abandoned. Maintenance is particularly complicated when components from several manufacturers have been assembled and programmed by a

[42] Eugene D. Lourey, "Systems Design for a Minicomputer-Based Library Data Management System," in *Applications of Minicomputers to Library and Related Problems*, ed. F. Wilfrid Lancaster, papers presented at the 1974 Clinic on Library Applications of Data Processing, 28 April to 1 May 1974 (Urbana-Champaign, Ill.: University of Illinois, Graduate School of Library Science, 1974), pp. 185–6. Weitzman gave a chart on typical values of MTBF (mean time between failures) for minicomputer components and peripherals. Only line printers (400 to 800 hours), card punches (200 hours) and impact keyboard printer terminals (300 to 1600 hours) have values in hundreds of hours; all of the other items have values in thousands of hours; Cay Weitzman, *Minicomputer Systems; Structure, Implementation, and Application* (Englewood Cliffs, N.J.: Prentice-Hall, 1974), p. 307.

systems house. In such cases, maintenance often is contracted out to another firm, which functions as a maintenance company. It is important to know where the maintenance unit is located and what the turnaround time is on the equipment. Because minis are modular, often a board can be pulled and a new one substituted while repairs are being made.

One other area of maintenance must be considered — software maintenance. Programs are rarely ever "finished" and completely "debugged." Arrangements should be made for the software to be maintained as necessary over the entire period of use.

Personnel

Staffing patterns change when an automated system is introduced. Sometimes a special implementation team is required if extensive initial data input is required for building a file or files.

Because the minicomputer is located in the library, a library staff member or members must be assigned the role of computer operator. In many libraries, the input operators can be trained to do the operator's tasks along with their other duties. The duties of the operator vary with the system configuration, the operating mode of the operating system software, and the nature of the application. For the simpler systems with simple executive monitors, the operator must attend the job flow fully. With a single batch operating system, the software does the job control. Cards still must be loaded to be read, tapes must be mounted, and paper in the printer must be alined. In any system the equipment must be powered up, the program must be loaded, and the system must be shut down each day. Files of tapes, disks, or cards must be stored, and a log must be maintained to keep track of them. The persons responsible for these tasks must be trained thoroughly by the system vendor. There should be comprehensive manuals for the training period and for reference during ongoing use. Complete system documentation should also be provided.

Time Frame

One recurring problem in automation projects has been poor estimation of the time involved in developing a system. It always has taken longer than anticipated. Certain variables affect the time it takes to develop a system. For example, it is quicker to buy a turnkey system than to develop a new system. Also, in developing a new system, it is quicker to contract the work to a commercial source than to do it in-house, if for no other reason than that a firm delivery date can be negotiated as part of the contract. As mentioned earlier, the extensiveness of the system software and the presence or absence of a compiler can affect the programming time.

The real key to fast, efficient development is using an experienced minicomputer programmer. Such a programmer will have a "minicomputer philosophy" and will not try to implement large-scale computer systems on the smaller machine. The programmer must shed his "batch" cloak and think "interactive online," for that is the mode to which minicomputers are conducive. If there is no such programmer on the agency data processing staff, it may be worth the time to train a programmer in minicomputers.

THE DECISION

When all the data have been gathered, reviewed, and evaluated, the time for decisionmaking has arrived. When the selection is made, the procurement procedure must get underway. As a Federal agency, the library must comply with Federal procurement regulations and procedures for ADP equipment.

Federal ADP Procurement

The longstanding policy of the Federal Government, as expressed in OMB Circular A–76, is reliance on the private sector for goods and services. This policy as it relates to ADP procurement is expressed in the Brooks Act (Public Law 89–306), "Procurement of ADP Resources by the Federal Government," which emphasizes that ADP requirements should be procured in a competitive manner.

Three agencies have specific responsibilities relating to ADP procurement. The Office of Management and Budget (OMB) is responsible for establishing policy and ensuring that the policies are being followed. OMB sees that agencies rely as much as possible on commercial ADP services and ensures that ADP equipment (when authorized) and services are procured in an efficient and orderly manner. Approval of new or expanded in-house ADP facilities must be obtained in accordance with the "new start" requirements of Circular A–76, before submission to OMB of the agency budget request that includes the necessary funds.

The General Services Administration (GSA) administers ADP procurement. It provides management guidance and is the authority for approving noncompetitive procurements and delegating procurement

authority to user agencies. GSA does not, however, become involved in determining whether an agency requirement is legitimate. GSA publishes lists with prices of equipment and types of services on its supply schedules. In general, any procurement, either on or off schedule, with a one-time or an annual cost of $50,000 or more, must be authorized by GSA.

The National Bureau of Standards is the third agency involved in ADP procurement. It provides necessary hardware and software standards.

Although some minicomputers appear on GSA schedules as office equipment, minicomputers are generally considered ADP equipment. In November 1975, the Commissioner of the Automated Data and Telecommunications Service of the General Services Administration discussed trends in minicomputer procurement. Just as large-scale computers and peripherals were purchased under centralized and volume procurements, "volume procurements of minicomputers must and will occur. The question to be resolved is what is the best method to use for these acquisitions."[43]

> In order to determine the best method for procuring a product or service, we in ADTS have to be aware of the marketplace and the industry . . . . We've gone from the mandatory requirements contracts for the entire government when buying peripherals, to indefinite quantity contracts with voluntary usage when buying minicomputers. We have not created new techniques, but we have been selective in the techniques we've used. The government has been the systems integrator, or industry has provided the systems integration, depending on the environment.
>
> I don't want to leave you with your thinking our evolution is complete. In our future volume procurements for minicomputers, we will specify the maximum amount that can be ordered under each indefinite quantity contract. That number will not exceed 8 to 10 times the guaranteed minimum order. This will allow an agency the flexibility it needs to meet its needs through the procurement, yet is reasonable for industry.[44]

A year later the whole emphasis for all ADP procurement had shifted. Instead of discussing methods of procuring equipment for Government use, the officials were speaking of relying on the private sector for products and services. This shift was largely a result of the Congressional hearings and report on the administration of the Brooks Act during its 10-year life. It was found that the true intent of the Brooks Act was not being carried out and recommendations were made to bring the course of Federal procurement back into line, i.e., use of the private sector and of fully competitive procurement.

In a paper delivered to the AIIE in November 1976 an OMB spokesman expressed the policy on use of the private sector as follows:[45]

> In the case of ADP, we feel that the policy is best served when agencies can satisfy their requirements by contracting for complete ADP services, and that Government acquisition and operation of facilities should be limited to those situations which can be justified as being in the national interest under the guidelines of Circular A–76.
>
> * * * * *
>
> In order to evaluate the feasibility and relative economy of contracting for ADP services, Government needs must be presented in a format suitable for evaluation and for use in a contract statement of work. This requires a fundamental change in the philosophy of requirement definition, since the in-house performance of ADP services has led agencies to define their needs in terms of the hardware, software, and personnel necessary to do the job. Requirements formulated on this basis cannot be properly evaluated to determine if the unique nature of the work necessitates in-house performance, nor can they be used to solicit competitive proposals from industry. The first step, therefore, in achieving greater reliance on private sources for ADP services is for Government agencies to develop and state their requirements in terms of the services performed, rather than the facilities needed to provide those services.
>
> Once the actual work being performed, or proposed to be performed, in a Government ADP facility is identified and described as a service, it can be examined to determine whether there is a compelling reason that it be done in a Federal facility by Federal employees. The fact that work may involve classified data, be part of the agency's basic program, or require privacy safeguards will not necessarily justify Government performance — industrial facilities have been cleared for classified work for many years and commercial data centers can meet privacy requirements as well as Government facilities. There must be a document justification in accordance with one of the exemption criteria of Circular A–76 to justify initiation or continuation of Government activities providing ADP services.
>
> * * * * *
>
> While this program calls for a significant change in Government practice, it does not reflect a change in policy — rather it is an application of long-standing policy to an area where that policy was not always appropriate under past conditions.

At the same conference the trend toward miniaturization — use of minicomputers — was discussed by the Director of the Office of ADP and Telecommunica-

[43] Theodore D. Puckorius, "Trends in Government Acquisition of High Technology ADP Equipment; [Speech]" in *Minicomputers: The Applications Explosion*, ed. David E. Debeau, proceedings of the American Institute of Industrial Engineers Conference held in Washington, D.C., 17–19 November 1975 (Los Angeles: Management Education Corporation, 1975).

[44] Ibid.

Newman, proceedings of the American Institute of Industrial Engineers Conference held in Washington, D.C., 1-3 November 1976 (Santa Monica, Calif.: Management Education Corporation, 1976), pp. 131–6.

tions Management of the Department of the Interior.[46]

There seems little dispute these days that the future technology will be greatly influenced by the interaction between communications and miniaturization, resulting in an accelerated trend toward interrelated minicomputers forming distributed processing networks. If we believe the communicators and minimanufacturers, this approach will not only bring data processing closer to the user, but at considerably less money.

* * * * *

Let's look at the Government ADP environment from the perspective of the past, rather than the future . . . . My generalizations are that:

a. There is a strong penchant for in-house processing capability.
b. RFPs are geared more to hardware specifications than to functional specifications.
c. There is a very strong reliance on costly benchmarks. The combination of hardware specifications and benchmarks gives us a warm feeling that we are acquiring the best configuration to do our job.
d. We think bigness in terms of hardware. Most of us have grown up in the syndrome created by the maxivendors and we follow the American tradition of wanting the biggest and the best. We may be kidding ourselves, however, to think that bigness and best are synonymous in today's technology.

* * * * *

[Therefore, although] technology is offering potential cost savings through interconnected miniaturization . . ., our RFPs are benchmark dependen . . . . The marketplace has expanded but our traditional methods of procurement do not let the broadened marketplace respond — it does not respond to our traditional benchmark requirements.

The speaker went on to suggest a model procurement that would open up competition. It involved developing an RFP built around users needs, rather than around a predetermined data processing scheme for satisfying those needs. The total marketplace would be asked to respond by submitting a detailed plan, including schedules and estimated pricing scheme, for satisfying the user needs. A team of evaluators would then review the proposals and select the most feasible approaches and best qualified contractors (on a very subjective basis). From this evaluation at least two contractors would be selected for final bid. During this step, a benchmark would be tailored to fit the specific marketplace invited to final bid. "The final contract award then would be based on lowest overall cost and benchmark performance."[47]

This discussion was in terms of numerous minicomputers combining for distributed processing. What of minicomputers used singly as a standalone system? The report of the hearings on the Brooks Act specifically speaks of minicomputers in several sections. One recommendation states that competitive procurement of minicomputers (or service contracts) should be used if possible instead of interim upgrades, add-ons, or replacements for large-scale systems.[48] Minicomputers were included in the category of smaller dollar value procurements (less than $250,000) which made up 56 percent of the 1975 procurement delegations. It was felt that these procurements cost GSA and the user agencies a disproportionate amount of time and resources as they were required to follow the same procedures used for major procurements.[49] The following recommendation was made.:[50]

Federal user agencies should be authorized to procure ADP resources, excluding CPUs, below $250,000 without specific delegation of authority from GSA as long as the agencies document that the procurements are fully competitive. Procurement of CPUs should always require a delegation from GSA.

At present these are just recommendations. Procurement regulations are constantly changing and evolving. The typical procurement of a minicomputer will still involve an alphabet soup of forms and regulations: FPMR 101–32, Public Law 89–306, OMB Circular A–76, F and D, DPA, S.S., M. and M., RFP, IFB, RFQ, nonmandatory schedules, mandatory FSS schedules, mandatory requirements contracts, and so on.

The system suggested in this book will lead the design team to the type of specifications required (functional specifications, technical specifications, or detailed model and make specifications). It should provide the rationale needed for approval requests and justifications and should lead to an efficient, effective system.

CHAPTER SIX

CONCLUSIONS

This book did not attempt to investigate the potential of the minicomputer in a Federal library. No proof was needed. There was no doubt of the ability of minicomputers to solve many problems and fill many needs of Federal and other libraries. The goal was to demonstrate to the reader this ability and to give guidelines for introducing a minicomputer into a specific library.

What advantages do minicomputers bring to a system? A summary of their attributes gives a good overview.

1. They allow *local control.*
2. The *mini attitude* is a positive, encouraging approach.
3. The mini can be in a *smaller, simpler system.*
4. *Modular system development* is possible.
5. *Custom configurations* are easily accomplished.
6. A mini system is *flexible* and *adaptable to change.*
7. Minis are *less costly.*

Besides these attributes, minicomputers lend themselves to online interactive (as opposed to batch) operations, which provide fuller, more responsive services to the user. Finally, minicomputers "fit in" with any automation environment; they can stand alone, they can perform as parts of networks, they can support networks, they can be connected to hosts as other "terminals," or they can serve in several of these capacities at once.

INITIATING MINICOMPUTER PROJECTS IN FEDERAL LIBRARIES

Okay. The book succeeded — you're sold. Now, how do you initiate a minicomputer project in your library?

THE LIBRARY'S ROLE

The library must take the first step. A problem or a need must be identified and the systems analysis/system design phase begun. The library may turn to its agency data processing unit for help at that point, or the help may come from an outside consultant. The system requirements are drawn up. The design model is used. The systems design document is prepared to describe alternative means of meeting system objectives and requirements. The alternatives are reviewed, and a decision is made.

Let us assume that the alternative chosen involves use of a minicomputer. The system specifications are prepared, and the library works closely with the agency procurement unit. RFPs are issued, proposals are reviewed and evaluated, and a selection is made. The contracts are negotiated and signed. The implementation phase follows.

Throughout this period the library administrators have kept their staff informed, sought their comments during the design phase, and performed initial training where needed. This function is critical to the ultimate success of the new system.

THE AGENCY'S ROLE

The parent agency can play an active or passive role. If staff are available, the agency data processing unit can take the main roles in the systems design team. If they do not have the resources to commit to a project of this scope, they should support the efforts of the library to hire an outside contractor or consultant. The data processing unit must contribute to the data gathering phase and give accurate assessments of what, if any, support (in people or equipment) the library can receive both at present and in the future.

The agency procurement unit will play an active role at various stages of the project. If a consultant is hired for the systems analyses, the procurement unit will handle the necessary procedures. After the decision has been made as to systems design, the procurement unit will oversee preparation of the RFP and will issue it. It will gather the proposals submitted and oversee the review, evaluation, and selection process,

benefits in efficiency and efficacy would be many. This concept should be uppermost in the minds of Federal library administrators as planning is done over the next few years.

IN CLOSING

Walter Curley summarized "what it takes to venture into a library computer program and to make it work."[4] Although his words are not very uplifting or positive, they are realistic and ring true. It is hoped that they will put any new minicomputer plans prompted by this book into perspective, and that they will temper raw enthusiasm with a cautious note of realism.

1. Recognize that hardware is the easiest thing to come by and software the most difficult. The equipment must work; must do what it is intended to do.
2. Know that time is your enemy until your computer program is up and operational.
3. Have the patience of a saint with your staff, your board, your public, your computer experts. Be supportive of staff and understanding about the adjustments which they must make to a new way of doing things.
4. Develop the guts of a cat burglar — you will need them. Once you have made a decision to be innovative with computers, everyone will be from Missouri until you show the promised and hoped-for results.

[4] Walter Curley, "Innovative Strategies in Systems and Automation," in *Library Automation: The State of the Art II,* eds. Susan K. Martin and Brett Butler, papers presented at the Preconference Institute on Library Automation sponsored by the Information Science and Automation Division of the American Library Association at Las Vegas, Nevada, 22–23 June 1973 (Chicago: American Library Association, 1975), p. 134.

working closely with the systems design team. Throughout, this unit will perform necessary coordination with the Federal agencies involved (i.e., GSA, OMB, etc.).

FEDERAL GOVERNMENT ROLE

The influence of the Federal Government is strong in the areas of budget, management, and procurement of ADP equipment. The attitudes of the Office of Management and Budget, the General Services Administration, and the National Bureau of Standards were discussed in Chapter Five. There are Federal regulations to follow, forms to complete, and procedures to carry out. The impact of these agencies in a library's purchase of a minicomputer is considerable. As stated above, the link to these agencies is the parent agency's procurement unit.

At the Governmentwide level, the Federal libraries as a group play a role. The Federal Library Committee has recognized this role and has supported model minicomputer projects in individual libraries. It has formed a working group on minicomputers and has sponsored this book. The main needs to be met are establishing communications and ultimately achieving close coordination among libraries. It is important that the knowledge and experience gained by one library be shared with others.

ROLE OF THE PRIVATE SECTOR

The role of private industry in the general area of minicomputers was discussed in Chapter Five. Vendors of library services and products have mounted little in the way of successful, ongoing marketing efforts. The market is there, but many vendors have not bothered to go through the paperwork required to get on a GSA schedule or don't have the patience or marketing budget to invest in the long and complicated bid and negotiation procedures involved in Government procurement. At the other end, many libraries have scorned commercial firms as being suspect because of their profit motives. Both vendor and client have much to gain from mutually fair and open relationships.

TRENDS IN FUTURE APPLICATIONS OF MINICOMPUTERS IN FEDERAL LIBRARIES

Almost every book ends with a statement on the future. The most important statement that can be made here is that there is a future for minicomputer applications in Federal libraries. This in itself is the main trend of the present and near future.

We predict that the future will see a trend in Federal libraries toward a distributed network of minicomputers. This network would not be so much a communications network as a network of decentralized data bases and decentralized processing.[1] Bowers envisions a

> ...concept of distributed processing, which holds that data processing is not most efficiently and effectively done in large, centralized computers, but rather should be divided among smaller, loosely-coupled machines. The division might be by geography or by type or task or both, and the coupling might consist of communications lines or a person carrying a reel of tape from one machine to another.[2]

Pezzanite described a similar approach at a workshop on computerized library networks given in Maryland.[3] He proposed a statewide distributed network. The hub of the network was a central processing unit that had a large-scale computer and maintained a large cataloging data base. The data base was to include a generalized data base using MARC tapes, as well as a union state data base. The unit would have "the responsibility of updating and disseminating the distributed data base [contributed by the member libraries] on a regular, cyclic schedule" as well as "the development and distribution of products required by members," such as card sets, book or COM catalogs, and photocomposition. Each member library would have a minicomputer to use for data capture, local processing, and maintenance of its own file. The original cataloging and the holdings would be sent to the central unit to update the master data base. Each library would be responsible for its own file and that file's integrity. Each member would have what Pezzanite described as "functional autonomy."

The viability and feasibility of such a distributed network among Federal libraries are certain. The

APPENDIX A

GLOSSARY

ACCUMULATOR
A hardware register that holds the results of arithmetic, logical, and I/O operations.

ACOUSTICAL COUPLER
A device that converts electrical signals into audio signals. It is used with a telephone handset for connecting to the public telephone network for data transmission.

ADDRESS
An identification (name, label, or number) for a register, location in storage, or other source or destination for data.

AMERICAN STANDARD CODE FOR INFORMATION INTERCHANGE (ASCII)
A standard code that represents characters by seven-bit-plus-parity codes; for use with various data processing systems, communication systems, and associated equipment.

ANALOG COMPUTER
A computer that operates on analog data by performing physical processes on these data. *Compare*: digital computer

ANALOG DATA
Data in continuous form, usually numerical quantities of physical variables such as voltage, speed, rotation, resistance, etc. *Compare*: digital data

ARITHMETIC UNIT
The part of the central processing unit that carries out computational and logical operations.

ASCII *see* AMERICAN STANDARD CODE FOR INFORMATION INTERCHANGE

ASSEMBLER
A computer program that prepares a machine language program by converting symbolic language codes into absolute operation codes and assigning absolute or relocatable addresses for symbolic addresses.

ASYNCHRONOUS
Occurring without regular or predictable time relationship.

ASYNCHRONOUS TRANSMISSION
Data transmission in which control is achieved by "start" and "stop" elements at the beginning and end of each character.

AUTOMATIC COMPUTER
A machine that manipulates symbols according to given rules in a predetermined and self-directed manner.

AUXILIARY MEMORY
(1) Data storage other than main storage on such a device as a magnetic tape unit or a direct access unit.
(2) A storage that supplements another storage. *See also*: mass storage

BASIC
A high-level, algebralike language designed for use in problemsolving by engineers, scientists, and others who are not professional programmers. It is available for interactive, time-sharing direct communications between terminal and host.

BATCH
(1) A type of input in which a number of similar input items or transactions are accumulated and processed together at one time.
(2) The sequential input of computer programs or data.
(3) The technique of executing a set of computer programs such that each is completed before the next program of the set is started, i.e., execution of computer programs serially.

BAUD
An abbreviation for "bit audible." A unit of signaling speed equal to the number of discrete conditions or signal events per second. Note: when the discrete condition is such that one element carries one bit, the baud rate is numerically equal to bits per second (BPS).

BCD *see* BINARY-CODED DECIMAL

BINARY-CODED DECIMAL (BCD)
A type of notation system where each decimal digit is represented by four binary digits (or bits).

BINARY DIGIT (BIT)
(1) One of the two numerals in the binary number system — zero or one. It may be equivalent to any characteristic, property, or condition in which there are only two possible conditions, such as on or off or yes or no.
(2) The kind of number used internally by computers. *See also*: machine language.

BINARY NUMBER SYSTEM
A number representation system using base-two notation, in which the only valid digits are zero and one.

BINARY SYNCHRONOUS TRANSMISSION
Data transmission in which character synchronism is controlled by timing signals generated at the sending and receiving stations. *Also called*: bisynchronous

BISYNCHRONOUS *see* BINARY SYNCHRONOUS TRANSMISSION

BIT *see* BINARY DIGIT

BITS PER INCH (BPI)
A measure of the density in which the number of bits of information are contained or written along an inch of magnetic tape.

BPI *see* BITS PER INCH

BUFFER
An area of internal storage or a hardware device used to store information temporarily during data transfers. It is used to compensate for a difference in rate of flow of data, or time of occurrence of events, when transmitting data from one device to another.

BUG
(1) A program defect or error.
(2) A mistake or malfunction.

BUS
A circuit or path over which data or power is transmitted; usually lines that connect locations or a single line that acts as a common connection among a number of locations.

CARTRIDGE TAPE
A type of magnetic tape in a special housing used for mass storage. It is similar to a tape cassette.

CASSETTE TAPE OPERATING SYSTEM
An operating system designed to use a cassette tape as the mass storage device.

CATHODE-RAY TUBE (CRT)
A vacuum tube similar to a television picture tube, used as a storage or a visual display device.

CENTRAL PROCESSING UNIT (CPU)
The unit of a computer that controls the interpretation and execution of instructions such as calculations and logic decisions. It is composed of the arithmetic unit and the control unit and functions directly with main memory. *Also called*: main frame

CENTRALIZED (COMPUTER) NETWORK
A computer network configuration in which a central node provides computing power, control, or other services. *Also called*: star network

CHANNEL
(1) A path along which signals can be sent.
(2) That part of a communications system that connects a message source with a message sink (that is, a terminal installation that receives and processes data). *See also*: information (transfer) channel
(3) A means of one-way transmission. *Compare*: circuit

CHIP *see* LSI CHIP

CIRCUIT
In communications, the complete electrical path providing one- or two-way communication between two points comprising associated go and return channels. *Compare*: channel

CLOCK
A device that generates periodic signals used for synchronization.

COBOL
An abbreviation for *C*ommon *B*usiness-*O*riented *L*anguage. A high-level language designed for use in business data processing applications.

CODE
(1) A set of unambiguous rules specifying the way in which data may be represented.
(2) In data communications, a system of rules and conventions according to which the signals representing data can be formed, transmitted, received, and processed.

COM *see* COMPUTER-OUTPUT MICROFORM

COMMUNICATIONS LINK
The means of connecting one location to another for the purpose of transmitting and receiving information.

COMPILER
A computer program that prepares a machine language program (object program) from a computer program written in another programming language (source language, usually a high-level language) by using the overall logic structure of the program or by generating more than one machine instruction for each symbolic state, or both, as well as performing the function of an assembler. A compiler usually contains its own library of closed routines.

COMPUTER NETWORK
An interconnection of assemblies of computer systems, terminals, and communications facilities. A complex consisting of two or more interconnected computing units.

COMPUTER-OUTPUT MICROFORM (COM)
A process in which computer information is output onto a microform (e.g., microfilm or microfiche) through a COM printer.

CONCENTRATOR *see* DATA CONCENTRATOR

CONFIGURATION
The group of devices that make up a computer or data processing system.

CONSOLE
The unit of a computer containing the control keys and certain special devices used by the operator for direct communication with the computer. It can be used to control the machine manually, correct errors, determine the status of the machine circuits, registers, and counters, determine the contents of storage, and revise manually the contents of storage.

CONTENTION SYSTEM
A system in which one or more terminals and the computer compete for use of the line; involves unregulated bidding for a line by multiple users. *Compare*: polling system

CONTROL UNIT

(1) The part of the central processing unit that directs the sequence of operations, interprets coded instructions, and sends the proper signals instructing other computer circuits to carry out the instructions.
(2) A device that controls the reading, writing, or display of data at one or more input/output devices. *See also*: input/output controller

CONVERSATIONAL MODE

The processes for communication between a terminal and the computer, in which each entry from the terminal requires a response from the computer and vice versa. This mode involves step-by-step interaction between the user and a computer.

CONVERSION

(1) The process of changing from one form of representation to another.
(2) The process of transferring information from one recorded medium to another.

CORE

A configuration of magnetic material used with current-carrying conductors to retain a magnetic polarization in either an "on" or an "off" state, for the purpose of storing data represented as a binary one (on) or zero (off). It is commonly used as main memory for computers; main memory is often called "core memory." *Also called*: magnetic core

COUNTER

A device, such as a register or storage location, used to represent the number of occurrences of an event.

CPU *see* CENTRAL PROCESSING UNIT

CRT *see* CATHODE-RAY TUBE

CTOS *see* CASSETTE TAPE OPERATING SYSTEM

CURSOR

A movable spot of light on a cathode-ray tube of a console or a display unit that indicates where the next character will be entered.

CYCLE

An interval of space or time in which one set of events or phenomena is completed.

CYCLE TIME

(1) The time to read (and restore) a single word in memory.
(2) The minimum time interval, in microseconds, between two successive accesses to a particular storage location.

DATA BASE

(1) The entire collection of information available to a computer system.
(2) A structured collection of information as an entity or collection of related files treated as an entity.

DATA CONCENTRATOR

A communications device that provides communications capability between many low-speed, usually asynchronous channels and one or more high-speed, usually synchronous channels. Usually different speeds, codes, and protocols can be accommodated on the low-speed side. The low-speed channels usually operate in contention, requiring buffering. The concentrator may have the ability to be polled by a computer, and may in turn poll terminals.

DATA ELEMENT

A class or category of data based on natural or assigned relationships.

DATA HIERARCHY

A data structure consisting of sets and subsets such that every subset of a set is of lower rank than the data of the set.

DATA STRUCTURE

The manner in which data are represented and stored in a computer system or program.

DBMS

An abbreviation for *D*ata *B*ase *M*anagement *S*ystem.

DEBUG

To detect, locate, and remove mistakes from a routine or malfunctions from a computer.

DEBUGGER

A systems software program designed to help the programmer determine causes of problems found during the running of his software. It features the ability to stop the executing program and determine the state of the machine at that time, i.e., the content of all memory locations and registers.

DEMODULATOR

A device that receives signals transmitted over a communications link and converts them into electrical pulses, or bits, that can serve as inputs to a data processing machine. *Compare*: modulator

DIAGNOSTICS

A program that facilitates computer maintenance by detecting and isolating malfunctions or mistakes.

DIGITAL COMPUTER

A computer that operates on digital data by performing arithmetic and logical processes on these data. *Compare*: analog computer

DIGITAL DATA

Information represented by a code consisting of a sequence of discrete elements. *Compare:* analog data

DIRECT ACCESS DEVICE
(1) A memory device that allows a particular data address to be accessed independently of the location of that address. The reference is to a location of a volume rather than relative to the previously retrieved or stored data. *Compare*: serial access
(2) A storage device in which the access time is effectively independent of the location of the data.
Also called: random access device

DIRECT MEMORY ACCESS (DMA)
A method of data transfer using a hardware device that sets up a high-speed data path to link memory with peripheral electronics.

DISK OPERATING SYSTEM (DOS)
An operating system designed to use a disk as a mass storage device.

DISK PACK
A removable direct access storage device containing magnetic disks on which data are stored.

DISKETTE *see* FLOPPY DISK

DISPLAY
(1) A presentation of data in human-sensible form.
(2) A device for visually presenting data from the computer to a user.

DISTRIBUTED NETWORK
A network in which all node pairs are connected, either directly or through redundant paths through intermediate nodes. *Compare*: fully distributed network. *Also called*: multistar network

DMA *see* DIRECT MEMORY ACCESS

DOS *see* DISK OPERATING SYSTEM

DUPLEX TRANSMISSION
Simultaneous two-way independent transmission in both directions. *Also called*: full-duplex *Compare*: half-duplex

E-TIME
The execution cycle. One of two basic machine cycles of the control unit. The instruction is performed during the execution cycle. E-time varies according to the length of time required to perform a specific instruction; for example, addition does not take as long as multiplication. *Compare*: I-time

EBCDIC *see* EXTENDED BINARY CODED DECIMAL INTERCHANGE CODE

EXTENDED BINARY CODED DECIMAL INTERCHANGE CODE
A system of codes for a set of 256 characters, each represented by a different eight-bit pattern.

FIELD
(1) A set of characters representing logical units or data elements.
(2) In a record, a specified area used for a particular category of data. It can be of fixed or variable length.

FILE
A collection of related records treated as a unit.

FILE LAYOUT
The arrangement and structure of data in a file, including the sequence and size of its components.

FILE MAINTENANCE
Keeping a file up to date by adding, changing, or deleting data.

FIRMWARE
Software instructions that have been more or less permanently burned into a ROM (read-only memory) or PROM (programmed read-only memory) chip.

FIXED-HEAD DISK
A mass storage device which uses a rigid, circular plate with a nonmovable read-write head for each track of the disk.

FIXED-LENGTH FIELD
A data field that has the same predetermined number of characters from record to record. *Compare:* variable-length field

FLAG
A character or other indicator that signals the occurrence of some condition.

FLIP-FLOP
A sequential switching circuit capable of storing one bit of information in one of two stable states. Flip-flops may be grouped to form storage registers, counters, shift registers, or other functional components.

FLOPPY DISK
A mass storage device in which the storage medium is a single flexible plate of Mylar material housed in a paper jacket. *Also called*: diskette

FORMAT
A specific arrangement of data.

FORTRAN
An abbreviation for *For*mula *Tran*slator. A high-level language designed for mathematical computations.

FULL DUPLEX *see* DUPLEX

FULLY DISTRIBUTED NETWORK
A network in which each node is directly connected with every other node. *Compare*: distributed network

GATE
A device having one output channel and one or more input channels, such that the output channel state is completely determined by the input channel states except during switching transients. Common logic gates are AND, NO, and NAND (not and).

HALF-DUPLEX
Alternate, one way at a time, independent transmission. *Compare*: duplex

HARDWARE
The physical equipment of a data processing system, as opposed to the computer program or method of use.

HEXADECIMAL NOTATION
A scheme in which hexadecimal numbers are used to represent four-bit patterns as a shorthand means. The hexadecimal number system uses a base of sixteen, with valid digits that range from 0 through F, where F represents the highest units position (15).

HIERARCHICAL (COMPUTER) NETWORK
A computer network in which processing and control functions are performed at several levels by computers specially suited for the functions performed, e.g., in factory or laboratory automation. *Also called*: tree network.

HOST
A computer attached to a network providing mainly services such as computation, data base access, or special programs or programming languages.

I-TIME
The instruction cycle. One of two basic machine cycles of the control unit. During the instruction cycle, the instruction register receives the next instruction in the stored program, the instruction is interpreted in preparation for its execution, and the location counter is adjusted to contain the address to the next instruction. *Compare*: E-time

IDENTIFIER
A symbol whose purpose is to identify, indicate, or name a body of data.

ILL
An abbreviation for *In*terlibrary *L*oan.

INDEX
(1) In data management, a table in the catalog structure used to locate data sets.
(2) In data management, a table used to locate the records of indexed sequential data sets.

INFORMATION (TRANSFER) CHANNEL
(1) The functional connection between the source and the sink data terminal equipment. It includes the circuit and the associated data communications equipment.
(2) The assembly of data communications and circuits, sometimes including a reverse channel.

INPUT/OUTPUT CONTROLLER
A device that directs the interaction between the processing unit and input/output devices. *See also*: control unit

INQUIRY
A request for information from storage.

INSTRUCTION SET
A set of operations that can be represented in a given operation code. *Also called*: instruction repertoire

INTERACTIVE
Pertaining to exchange of information and control between a user and a computer process. In the interactive mode, direct communication is established and a conversation or dialogue is often undertaken. *See also*: conversational mode

INTERFACE
A shared boundary. An interface might be a hardware component linking two devices, or a portion of storage or registers accessed by two or more computer programs. An interface enables devices to transfer information to and from one device or program and another.

INTERNAL STORAGE
The addressable storage directly controlled by the central processing unit. *Also called*: main memory

INTERPRETER
(1) A program that translates and executes each source language statement before translating and executing the next one.
(2) A device that prints on a punched card the data already punched in the card.

INTERRECORD GAP (IRG)
The area at the end of a block or record on a blank tape or disk. It is created during the start-up and the stop time, during which no data are recorded.

INTERRUPT
To stop a process in such a way that it can be resumed.

INTERRUPTION
A break in the normal sequence of instruction execution which causes an automatic transfer to a preset storage location where appropriate action is taken.

INVERTED FILE
In information retrieval, a method of organizing a cross-index file in which keywords identify records.

INVERTED TABLE LOOK-UP
The process of searching a table whose sequence or order is other than that of the original table.

I/O
An abbreviation for *I*nput/*O*utput.

IRG *see* INTERRECORD GAP

JOB
A specified group of tasks prescribed as a unit of work for a computer. A job usually includes all necessary programs, linkages, files, and instructions to the system.

JOB-ORIENTED TERMINAL
A terminal designed to receive source data in an environment associated with the job to be performed and capable of transmission to and from the system of which it is a part.

KEY

One or more characters in an item of data that are used to identify it or control its use.

KEYWORD
One of the significant and informative words in a title or document, describing the content of that document.

LINKED LIST RELATIONSHIP
A configuration of ordered items, which usually do not occupy contiguous locations in online or offline memory.

LOGICAL ENTRY
All the data input to the data base in one logical grouping.

LOGICAL FILE
A collection of one or more logical records.

LOGICAL RECORD
A collection of items independent of their physical environment. Portions of the same logical record may be located in different physical records.

LOOP NETWORK
A computer network in which each computer is connected to adjacent computers. *Also called*: ring network

LSI CHIP
A small integrated-circuit package containing many logic elements. Large-scale integration (LSI) densities can vary from 500 to 10,000 transistors per chip.

MACHINE LANGUAGE
A binary language or code used directly by a computer.

MACRO
An instruction in a source language, equivalent to a specified sequence of machine instructions.

MAGNETIC CORE *see* CORE

MAIN FRAME *see* CENTRAL PROCESSING UNIT

MAIN MEMORY
(1) The general-purpose storage of the central processing unit that can be accessed directly by the operating registers. It stores both the data on which to be operated and the program dictating the operations to be performed.
(2) All program-addressable storage from which instructions may be executed and from which data can be loaded directly into registers.
Also called: main storage and working storage

MARC
An abbreviation for *Ma*chine-*R*eadable *C*ataloging.

MASS STORAGE
Data storage other than the main memory, usually devices that have large capacities, such as magnetic tape or disks. *Also called*: auxiliary storage

MEAN TIME TO FAILURE (MTTF)
A measurement based on a ratio of the operating time of equipment to the number of observed failures. *Also called*: mean time between failures (MTBF)

MEAN TIME TO REPAIR (MTTR)
A measurement that relates to the normal repair time for a piece of equipment.

MEMORY
A unit of the computer used to store information received through an input unit or developed during the processing of data. The information can be brought out of storage for use without being destroyed. *Also called*: storage or store

MESSAGE SWITCHING
A method of handling messages over communications networks. The entire message is transmitted to an intermediate point (a switching computer), stored for a period of time, and then transmitted towards its destination. The destination of each message is indicated by an address integral to the message.

MICROCOMPUTER
A computer with a microprocessor as its central processing unit.

MICROPROCESSOR
An LSI central processing unit on one or a few chips.

MINICOMPUTER
A physically small, relatively inexpensive, general-purpose computer that can operate in a regular environment with as much peripheral and system support as necessary to meet the requirements of the application.

MODEM
An abbreviation for *Mo*dulator-*Dem*odulator. A device that modulates and demodulates signals transmitted over communication facilities.

MODULATION
The process by which some characteristic of one wave is varied in accordance with another wave or signal. This technique is used in data sets and modems to make business machine signals compatible with communications facilities. It converts digital data for transmission on analog telephone lines and for recovering the digital information at the receiver. *Compare*: demodulator

MOS
An abbreviation for *M*etal *O*xide *S*emiconductor, a kind of material used in constructing chips.

MOVABLE-HEAD DISK
A mass storage device that uses as a medium a rigid, circular plate with a movable read-write head that positions itself over the appropriate track of the disk.

MTBF *see* MEAN TIME TO FAILURE

MTTF *see* MEAN TIME TO FAILURE

MTTR *see* MEAN TIME TO REPAIR

MULTIPLEX MODE
A means of transferring records to or from low-speed input/output devices on the multiplexer channel, by interleaving bytes of data. The multiplexer channel sustains simultaneous input/output operations on several subchannels.

MULTIPLEXER CHANNEL
A channel designed to operate with a number of input/output devices simultaneously.

MULTIPOINT NETWORK
A configuration in which more than two terminal installations are connected.

MULTIPROCESSING
A configuration of two or more central processors that can be independently initiated and have access to a common, jointly-addressable memory. Each processor can operate simultaneously, either on segments of the same job or on entirely different jobs.

MULTIPROGRAMMING
A resource management system in which an executive routine allocates the resources of the computer to many programs concurrently. It is composed of procedures for handling numerous routines or programs seemingly simultaneously by overlapping or interleaving their execution.

MULTISTAR NETWORK *see* DISTRIBUTED NETWORK

MULTITASKING
(1) A program design strategy in which the various logical elements making up a program are written so that they may operate asynchronously with respect to one another.
(2) Procedures in which several separate but interrelated tasks operate under a single program identity and may use common routines, data space, and disk files.

NETWORK
(1) An interconnected or interrelated group of nodes.
(2) In teleprocessing, a number of communication lines connecting a computer with remote terminals.

NODE
(1) An end point of any branch of a network, or a junction common to two or more branches of a network.
(2) Any station, terminal, terminal installation, communications computer, or communications computer installation in a computer network.

OCR *see* OPTICAL CHARACTER RECOGNITION

OFFLINE
Pertaining to equipment or devices not under control of the central processing unit. *Compare*: online

OFFLINE SYSTEM
In teleprocessing, that kind of system in which human operations are required between the original recording functions and the ultimate data processing function. This includes conversion operation as well as the necessary loading and unloading operations incident to the use of point-to-point or data-gathering systems.

ON-DEMAND SYSTEM
A system from which information or service is available at time of request.

ONLINE
Pertaining to equipment or devices under control of the central processing unit. *Compare*: offline

ONLINE DATA PROCESSING
Data processing in which all changes to relevant records and accounts are made at the time that each transaction or event occurs. *Compare*: batch processing

ONLINE SYSTEM
(1) In teleprocessing, a system in which the input data enters the computer directly from the point of origin or in which output data are transmitted directly to where it is used.
(2) A system that eliminates the need for human intervention between source recording and the ultimate processing by a computer.

OPERATING SYSTEM
Software that controls the execution of computer programs and may provide scheduling, debugging, input/output control, accounting, compilation, storage assignment, data management, and related services.

OPTICAL CHARACTER RECOGNITION (OCR)
Machine identification of printed characters through use of light-sensitive devices.

PAGE
A segment of a program or data, usually of fixed length, that has a fixed virtual address but can in fact reside in any region of the computer's working storage.

PARITY
A simple form of error detection in which one nondata bit is added to the data bits in a character so that the total number of "one" bits is either always even or always odd.

PARITY BIT
A check bit appended to an array of binary digits to make the sum of all the binary digits, including the check bit, always odd or always even.

PARITY CHECK
A check that tests whether the number of ones (or zeros) in an array of binary digits is odd or even.

PERIPHERAL
In a data processing system, any unit of equipment, distinct from the central processing unit, which may provide the system with outside communication.

PHYSICAL RECORD
A group of words, characters, or digits held in one section of an input/output medium or store and handled as a unit.

PIO *see* PROGRAMMED INPUT/OUTPUT

POINT-TO-POINT NETWORK
A network configuration in which a connection is established between two, and only two, terminal installations.

POINTER
An identification, as represented by a name, label, or number, for a register, location in storage, or any other data source or destination. Loosely, the address of the next record.

POLLING SYSTEM
A system in which each of the terminals sharing a communications line is periodically interrogated to determine whether it requires servicing.

PRIMARY STORAGE *see* MAIN MEMORY

PROCESS CONTROL
Pertaining to systems whose purpose is to automate continuous operations.

PROCESSOR *see* CENTRAL PROCESSING UNIT

PROGRAM
(1) A series of actions proposed in order to achieve a certain result.
(2) A plan and operating instructions needed to produce results from a computer.

PROGRAMMED INPUT/OUTPUT (PIO)
A method of data transfer that makes use of program instructions rather than hardware devices to control the transfer of information between the central processor and an external device.

PROM
An abbreviation of *P*rogrammable *R*ead *O*nly *M*emory. A kind of chip that is not recorded during its manufacture, but instead requires a physical operation to program it. Some PROMs can be erased and reprogrammed through special physical processes. *Compare*: ROM

PROTOCOL
A formal set of conventions governing the format and relative timing of message exchange between two communicating processes.

RANDOM ACCESS DEVICE *see* DIRECT ACCESS DEVICE

READ-ONLY ACCESS
The sharer may read the data set but he may not change it in any way.

REAL TIME PROCESSING
The processing of information or data rapidly enough that the results of processing are available in time to influence the process being monitored or controlled.

RECORD
(1) A collection of related items of data, treated as a unit.
(2) A collection of fields.

REGISTER
(1) A device capable of storing a specified amount of data, such as one word.
(2) A temporary storage device used for one or more words to facilitate arithmetical, logical, or transferral operations.

REMOTE ACCESS
Pertaining to communication with a data processing facility by one or more stations that are distant from that facility.

REMOTE BATCH PROCESSING
A procedure in which computer programs or data are entered into a remote terminal for transmission to the central processor. This allows various systems to share the resources of a batch-oriented computer.

RFP
An abbreviation for *R*equest *F*or *P*roposal.

RING NETWORK *see* LOOP NETWORK

ROM
An abbreviation of *R*ead *O*nly *M*emory. A kind of chip that has all of its circuits, e.g., logic elements or data, recorded as it is manufactured and can never be erased.

SDI
An abbreviation for *S*elective *D*issemination of *I*nformation.

SEMICONDUCTOR MEMORY
A memory whose storage medium is a semiconductor circuit.

SERIAL ACCESS
(1) Pertaining to the sequential or consecutive transmission of data to or from storage.
(2) Pertaining to the process of obtaining data from, or placing data into, storage, where the time required for such access depends on the location of the data most recently obtained or placed in storage. *Compare*: direct access device

SHARED FILE
A direct access device that may be used by two systems at the same time; a shared file may link two systems.

SINK
(1) The point of use of data in a network.
(2) A data terminal installation that receives and processes data from a connected channel.

SOFTWARE
A set of programs, procedures, and possible associated documentation concerned with the operation of a data processing system.

STACK
(1) A block of successive memory locations that are accessible from one end on a last-in-first-out basis. The stack is coordinated with a stack pointer that keeps track of storage and retrieval of each byte or word of information in the stack. The words "push" (move down) and "pop" (retrieve the most recently stored item) are used to describe its operation.
(2) A hardware device composed of a collection of registers with a counter which serves as a pointer to indicate the most recently loaded register. Registers are unloaded in the reverse of the sequence in which they were loaded.

STAR NETWORK
A computer network with peripheral nodes all connected to one or more computers at a centrally located facility. *See also:* centralized network

STORAGE MEDIUM
The material on which data are stored, e.g., magnetic and paper tapes, disks, and magnetic core.

SUPERVISOR
A control routine or routines through which the use of resources is coordinated and the flow of operations through the central processing unit is maintained.

SYSTEMS ANALYSIS
The study of all of the components, operations, data, information and material flow, work environment, etc., that constitute the existing system.

TABLE
A collection of data in which each item is uniquely identified by a label, by its position relative to the other items, or by some other means.

TAPE OPERATING SYSTEM
An operating system designed to use magnetic tape as the mass storage device.

TASK
A unit of work for the central processing unit, from the standpoint of the control program.

TASK MANAGEMENT
Those functions of the control program that regulate the use by tasks of the central processing unit and other resources.

TELECOMMUNICATIONS
(1) The transmission of signals over long distances, such as by telegraphy, radio, or television.
(2) Data transmission between a computing system and remotely located devices via a unit that performs the necessary format conversion and controls the rate of transmission.

TELEPROCESSING
(1) A form of information handling in which a data processing system uses communication facilities.
(2) The processing of data that is received from or sent to remote locations by way of telecommunications lines.

TERMINAL
(1) A point in a system or communications network at which data can either enter or leave.
(2) Any device capable of sending and receiving information over a communication channel.

TIME-SHARING
(1) A method of using a computing system that allows a number of users to execute programs concurrently and to interact with the programs during execution. Although the computer actually services each user in sequence, the high speed of the computer makes it appear that the users are all handled simultaneously.
(2) Pertaining to the interleaved use of the time of a device.

TIME-SLICE
A designed interval of time during which a job can use a resource without being preempted.

TIME-SLICING
A feature that can be used to prevent a task from monopolizing the central processing unit and thereby delaying the assignment of CPU time to other tasks.

TOS *see* TAPE OPERATING SYSTEM

TREE NETWORK *see* HIERARCHICAL NETWORK

TTY
An abbreviation for *Teletypewriter* equipment.

TURNKEY SYSTEM
A commercial on-the-shelf package that includes the minicomputer, peripherals, and software necessary for a specific application, complete and ready to use upon installation.

VARIABLE-LENGTH FIELD
A data field that can vary numbers of characters from record to record. *Compare*: fixed-length field

VIRTUAL MEMORY
A method of storage access involving transfer of information one page or more at a time between primary and secondary memory, and allowing the programmer to address total storage without regard to whether primary or secondary storage is actually being addressed.

VIRTUAL OPERATING SYSTEM (VOS)
An operating system designed to use a virtual memory mass storage technique.

VOS *see* VIRTUAL OPERATING SYSTEM

WORD
(1) A character string or a bit string considered as an entity.
(2) A group of characters occupying one storage location in a computer. It is treated by the computer circuits as an entity, by the control unit as an instruction, and by the arithmetic unit as a quantity.
(3) The smallest addressable unit in main memory.

WORKING STORAGE
In programming, storage locations reserved for intermediate results. *Also called*: main memory

ZEBRA LABEL
A label with preprinted lines in coded patterns which are read by a light pen (a photocell device). *Also called*: bar-encoded label

APPENDIX B

LIBRARY OF CONGRESS SYSTEMS SPECIFICATIONS FOR PROCUREMENT OF MINICOMPUTER SYSTEMS

DESIRED/OPTIONAL WEIGHTING

	SECTION E	REFERENCE	
A. COMMUNICATIONS			5%
1. Switched network operation	II 2.b.1.c	6	
2. Remote batch concurrent with interactive applications	II 2.b.1.d	6

SECTION F

I. SYSTEM SPECIFICATIONS

This RFP is intended to be a "System Specification" rather than a "Hardware Specification." Overall system requirements and individual configuration requirements have been described so that each prospective vendor will have the capability to propose the most effective approach for his particular product line. It would not be in the best interest of LC to circulate an RFP containing a list of specific model numbers, core sizes, and so on. For a procurement of this kind, it is most useful to rely on the unique problem-solving resources of minicomputer-oriented vendors and OEM's to prescribe a set of hardware and system software which will meet or exceed LC's response and reliability requirements.

A. Global Requirements (common to all systems covered by this procurement).

1. System Architecture

a. The systems proposed must be multilingual and multiprogramming computer systems capable of supporting interactive program development. There shall be a minimum of two terminals available for development of applications code but not necessarily concurrent with any given application.

b. To accommodate changes in workload, the systems (hardware and software) *must* allow modular increments in hardware, i.e., able to utilize more or less of any of the individual hardware components (except the cpu) and more or less cpu memory capacity by field modification.

c. The proposed systems must include an operating system which permits effective control of routine operations as well as unscheduled operations, e.g., recovery.

d. The systems proposed must communicate with system users, e.g., via operating system commands, a text editor, a language processor and interactive debugger.

e. The architecture and configuration of each proposed system must enable each system to provide a response time to each user terminal of not more than ten (10) seconds during sustained peak load operation (the functional descriptions of each of the six individual systems provide sufficient information for Bidders to derive "worst-case" and sustained peak load performance requirements for each system).

f. The system proposed must have software compatibility across all configurations of a single mainframe type or a computer "line," if such configurations are proposed.

2. System Hardware

a. *Mainframe or CPU.* Each proposal shall include relevant details such as bandwidths, buss structure, multiplicity of data paths, and control paths, instruction repertoire and timings, "intelligent" components, interrupt structure, registers, and performance enhancement strategies.

(1) The fundamental unit of internal data movement must be a "word" of at least 16 data bits plus any system bits such as parity, etc.

(2) There must be at least four (4) general purpose registers usable by application programs; sixteen (16) registers are preferred. Describe methodology for using registers as accumulators and for indexing.

(3) The upper and lower limits of memory must be explicity stated. These limits should be a function of both hardware and system software requirements (i.e.,

for the operating system, compilers etc. specified for this procurement, what is minimum memory required and maximum memory supported).

(4) The basic memory cycle time must be one microsecond or less and the effective memory cycle time due to memory configurations such as interleaving or cache memory paging must be stated in detail with any assumptions used such as hit rate or instruction mixes.

(5) The following features must be included:

(a) program accessible clock

(b) automatic program load

(c) memory protection

(d) automatic error detection

(e) automatic power failure detection

(f) automatic restart from power failure with no loss of memory.

(6) Illustrate using assembler source code statements and in a high-level language such as COBOL, FORTRAN or PL/1 the necessary instructions required to perform the following tasks. For each task, state the time required for execution assuming no interruptions occur:

(a) Move 1601 bytes from one area of memory to another area of memory.

(b) Compare a character string of 329 bytes to another string of the same length and branch if not equal.

(c) Compare one binary value to another binary value and branch if not equal. Both values are initially stored in memory.

(d) Branch to a location in memory having saved the address of the next instruction (so that a return could be executed).

(e) Decode and add the following *character strings* together and encode the result back into a character string. Timing should be given for each step in the process (i.e., decode, add, encode.)

123,932,480.63
1,420.64

(f) Specify the time required to access a physical block of data from a disk file considering the operating system overhead and hardware limitations. Assume no file management system.

(7) State whether processor instruction set is hardwired or microcoded.

(8) State whether any of the following desired instruction types are available:

(a) Immediate data (i.e., data available in instruction word).

(b) Stack operations (push, pop, etc.).

(c) Operations on packed, signed, non-integer (i.e., real) data.

(d) Byte addressing without having to load into register and shift.

(e) Code translation and string edit.

b. *Communications*

(1) Remote Batch

(a) The proposed system must be capable of communicating as a remote batch terminal and contain a minimum of two channels.

(b) As a remote batch terminal, the proposed systems must interface via bisynchronous communication protocol to an IBM 370 Model 158 using 2780 bisync or HASP work station protocol.

(c) The capacity to use a private line service for remote batch communications is mandatory. It is also desirable to have the capacity to use a switched network.

(d) It is desirable that the proposed systems be able to support concurrent operations of remote batch and interactive applications terminals.

(e) Terminal controllers or multiplexors must be capable of accommodating up to at least 60 asynchronous concurrent connections.

(f) Detailed information of the preferred characteristics of the communication channels follows. If a vendor cannot meet all of the preferred specifications he should specify which are not met and why his proposed system will be better or more useful to LC.

c. *Communication Channels*

(1) *Synchronous Channel*

(a) The proposed system shall have a Transmitter/Receiver capable of interfacing with modems whose input characteristics conform to one or more of the following at a transmission rate of at least 9600 bps:

1. EIA RS-232-C, RS-334, RS-269A
2. CCITT Recommendation V. 35
3. WECO 303 (Bell 303) as described in AT&T Publication 41302 "Wideband Data Stations, 303 Type."

When more than one of the above is available the selection of the particular interface shall be done by external cable changes and/or modular replacement of output circuit drivers/receivers at the LC facility.

(b) The synchronous channels shall be capable of handling 2780 bisynchronous protocol or HASP work station protocol. A complete and detailed description of this portion of the system is requested to include hardware interfaces, software supplied or required and any limitations.

(c) The vendor also must supply a cable and signal connection diagram for this section identifying the type connector being proposed and its signals. This will enable LC personnel to adequately determine if the proposed system is suitable.

(d) A desirable option would be the adaptability to several of the new bit oriented, full duplex protocols listed below:

1. FED-STD-1020(A) EIA RS-422 Balanced
2. FED-STD-1030(A) EIA RS-423 Unbalanced
3. FED-STD-1031 (Proposed) EIA XYZ Physical for "Analog" facilities
4. FED-STD-1029 (Proposed) EIA-ABD
5. FED-STD-1040 (Proposed) CCITT X. 21 Public digital networks.

(e) The vendor shall describe any loopback testing facilities available for determining if the computer interface is operating correctly.

(2) *Asynchronous Channels*

(a) The asynchronous channel shall interface with the processor or memory on a character basis. The transmitter shall have a parallel loaded buffer and serial output. An overrun error signal is desirable.

(b) The speed range shall be from a minimum of 110 baud to a maximum of 9600 baud rate.

(c) It is desired that the Transmitter/Receiver be designed to allow software to select the baud rate.

(d) Even, odd, or a no parity scheme is required and each Transmitter/Receiver pair shall generate, check or inhibit parity as determined by software.

(e) The character length shall be selectable to five, six, seven, or eight bits.

(f) The Transmitter/Receiver pair shall select one or two stop bits in addition to one start bit. One and one half stop bits may be utilized if two stop bits are selected for a five bit character.

(g) The modem control signals shall conform to RS-232C for asynchronous communications to be used with Bell 113 A/B, 103 and 202 S/T modems. A detailed description must be part of the proposal identifying connector types and signal pin connections.

(h) The proposal must describe any loopback testing facilities available for determining if the computer interface and multiplexor is operating correctly.

(i) Terminal interfaces must include the standard RS-232C interface.

(j) Terminal ports must accept either hard-wire or service through a dial up or hard wired modem. All these are required.

(k) Acceptable data rates must include 300, 1200, 2400, 4800 and 9600 bits per second.

d. *Peripheral Devices*

(1) CRT Terminals

(a) Keyboard must provide, as a minimum, the standard ASCII 96-character subset. Proposal shall include a table showing the CRT image of each of the 96 characters. Furthermore, the system must be capable of recognizing, transmitting, processing, storing, retrieving, displaying, and printing a full alphanumeric upper and lower case character set.

(b) CRT screen display area must be approximately nine (9) inches wide by seven (7) inches high as a minimum.

(c) CRT screen display area must have a capacity of not less than 1,920 characters displayed at not less than 80 characters per line.

(d) It is desired that CRT display characters consist of, or be equivalent to, a dot matrix of not less than 7 × 9 dots per character.

(e) The CRT display must be fully buffered and the refresh rate must be sufficient to maintain full intensity of each individual character over the entire display area without flicker or other distortion.

(f) The CRT unit must provide a cursor which functions as a visible positional indicator. It must be possible for the terminal operator to change the position of the cursor—left, right, up, down—by means of function keys on the CRT keyboard unit. Also, it is desirable to have the ability to tab or skip the cursor ahead to positions previously determined by the application program.

(g) Under program control, it is desirable to emphasize or highlight individual characters or character positions by means of high-low dual intensity reverse polarity or blinking, and it must be possible by program control to protect selected character positions from being modified.

(h) It is desired that the CRT unit have the ability to accept from the currently executing application program a visually formatted data entry screen display; project that display on the CRT screen in protected mode; then, without further CPU attention, allow the terminal operator to key-enter data into the specified input fields and to selectively re-key into these fields for

correction of errors visually detected by the terminal operator; and finally, when initiated by terminal operator action transmit only data currently displayed in the input field locations.

(i) CRT terminal must have an RS-232-C communications interface supporting user-selectable data transfer rates including 300 and 1200 baud.

(j) In addition to the terminal specified in (a) through (i) above, a software compatible alternative terminal not having lower-case capability is desirable. LC may choose to install a lower cost alternate terminal in situations where upper/lower case capability is not required.

(k) It is desirable to support the Library of Congress MARC II character set. This character set utilizes the parity bit to derive characters over and above the standard ASCII characters. It is requested that this capability be addressed.

(1) The CRT system must have a minimum of 10 function keys associated with it to enable selection of user functions. This requires the function keys to be identifiable by the applications code. It is desired that these keys be internal to the CRT keyboard but proposals for a co-located function key box will be entertained.

(m) It is desired that the CRT have an input I/O port which essentially parallels the keyboard. It shall conform to RS-232C serial transmission and be of suitable baud rate to accommodate a bar code wand reader or OCR reader with ASCII output.

(n) The CRT must have an output I/O port which shall be capable of transmission to the document printer specified in paragraph d. (5). This port will be used for printing the screen image.

(o) A desirable option is a terminal such as the one described above but with a 58 line × 80 character display for word processing applications. Refer to section 3.g for details of word processing.

(2) Direct Access Storage Devices

(a) User data/program storage

- System capacity for at least four separate online disk storage devices, each with removable data storage media (disk pack) "physically" compatible with IBM 3330 packs, IBM 2314 or CDC 9876 Trident packs. The average and maximum disk access times shall be stated including seek times and rotational latency. Average access time is defined as seek time across one-half of tracks plus one-half total rotational delay and shall not be greater than 50 millisec.
- System capacity to be not less than 300 million bytes of concurrently online direct access user data storage.
- System (disk subsystem in conjunction with operating system I/O drivers) must be capable of recognizing and bypassing bad tracks. Bidder must describe methodology of this capability.

(b) Systems residence device (optional)

- In view of the relatively large number of concurrent users to be supported, it is anticipated that bidders will find it desirable to include in their proposed system configuration a high-performance system residence device for program overlays, swap space, and so on. Because this device is optional, its detailed specifications are left up to the discretion of the individual bidder.

(3) Magnetic Tape Drives (optional)

(a) System must be capable of supporting up to four (4) tape drives in increments of one, starting with one drive. These drives must have the following characteristics:

(1) 9-track

(2) 800 or 1600 bpi — Preferably 1600 bpi

(3) 75 inches per second read/write speed minimum

(4) 2400 foot reel capacity

(5) ANSII compatible

(6) IBM readable

(b) In order to reduce media inventory and minimize operator intervention, LC is considering *not* including magnetic tape drives in these minicomputer systems. Bidder shall describe the impact (if any) this action would have in regard to each proposed system with particular attention given to aspects of system reliability, operation, and maintenance.

(4) Line Printer

(a) Each system will be equipped with one line printer.

(b) The sustained printer speed must be 200 lines/minute or better. Printer speed is defined as the print rate using a standard ASCII set of 96 characters and printing on all 132 print positions with equal use of all characters.

(c) Six lines/inch capability is required with six or eight lines/inch desirable.

(d) There must be a minimum of 132 print positions.

(e) The printer must be able to print mutiple copies up to six-part forms.

(f) The printer must be equipped with vertical and horizontal alignment controls for special forms, carriage control, and line feed suppression.

(g) The printer must have an adjustable forms width capability to accommodate forms ranging from 11 inches to 14 7/8 inches

(h) In reference to the extended character set it is requested that the line printer interface be such that it would not preclude the use of a full 8 bit code transmission to accommodate the MARC II character set.

(5) Document Printer

(a) There should be a minimum of 80 print positions with a capability of transmission of at least 30 characters per second.

(b) Standard 96 character ASCII (includes upper/lower case).

(c) Multi-part form capability is desirable.

(d) Character formation/impression mechanism must produce clear, "crisp" characters which will reproduce satisfactorily on Xerographic process office copier machines. Bidders shall include in their proposals a sample page printed by the document printer they are proposing.

(e) Printer must be capable of being located and operated remotely via the communications subsystem.

(f) In addition to document printer specified in (a) through (e) above, a software compatible alternative not having lowercase capability must also be operationally available. LC may choose to install lower-cost alternate document printers in situations where upper/lower case capability is not required.

(g) Additional capabilities are desired for the word processing subsystem explained in section 3. g. These are as follows:

(1) Variable pitch (either 10 or 12) and have readily changeable typefonts (not to exceed 5 minutes change time).

(2) In addition to upper/lower case alpha and numeric, the special symbols period, comma, colon, semicolon, plus, section, cent, parenthesis, brackets (squared), quotation, asterisk, question mark, number, exclamation mark, percent, dollars, dash, underline, slash and apostrophe are required.

(h) It is requested that the MARC-II character set discussed in paragraph d. (1) (k) be addressed here also.

(6) IBM Channel Interface

It is highly desirable to have the capability of interfacing the proposed systems to the IBM 370 via a selector and/or multiplexor channel. Response to this requirement should be documented evidence as to both hardware required and software available to accommodate the hardware. Both the minicomputer and IBM 370 system requirements and prerequisites should be identified along with data rate limitations.

3. System Software

General

a. *Operating System*

(1) A complete, fully supported operating system is required that is capable of supporting all peripherals and managing all system resources. This operating system must be capable of supporting a minimum of 60 concurrent interactive terminal users executing a mix of application procedures. If the terminal support is not part of the operating system describe any communication software available to perform this function. Areas of interest include buffer size requirements, amount of memory required for the package and interface to high-level languages.

(2) Both generic and specific program references to the line printer and other devices are desirable.

(3) All peripherals must be accessible through software from terminals.

(4) It is desirable to have a priviliged class of users permitting access and modification of system functions that are not available to non-privileged users.

(5) It is desirable to have a capability to dynamically "tune" the operating system to optimize performance for changing workloads.

(6) It must be possible to deny certain users access to certain system resources, such as disk space and CPU time.

(7) Program development must be possible from a minimum of two terminals.

(8) Capability MUST be provided for disk storage file backup. Offerors in responding should provide a measure of the time required to perform backup. Show all calculations and list the assumptions used for these calculations.

(9) A software library facility is required for frequently used programs.

(10) It is desired that it be possible to assign user priorities and for the system manager to define limits on user activity.

(11) Terminals must be addressable so that the operator can communicate with, and as a privileged user, interrupt individual users.

(12) Spooling to disk for line printer output is mandatory.

(13) There must exist a comprehensive file management system.

(a) Binary data as well as formatted data must be storable on disk and magnetic tape.

(b) File accessing from a program must be device independent.

(c) File structure must be language independent. Files created in one language must be accessible by other(s).

(d) Files created in batch mode must be fully compatible with and accessible in multiple user mode and vice versa.

(e) Files must be sharable. More than one user must be able to access the same file concurrently. Protection *against* concurrent access via user option must be also available.

(f) Record formats supported should include fixed, fixed block, variable, and variable blocked.

(g) File access methods supported should include sequential, index sequential, random, and direct.

(h) Bidders shall describe the file allocation methodology of their software, stating how this allocation methodology functions in a multi-user online interactive environment.

(i) If the requirements (a) through (h) above require a DBMS, bidders shall provide complete functional and operational description of their proposed DBMS (see item "f" below). Particular emphasis shall be placed upon the performance impact of such software.

(j) The file management system *must* have the capability of generic and approximate keyed retrieval. Generic is defined as having one or more of the leading characters of the key and approximate is defined as searching for the closest key such that

$KEY_R \geq KEY_F$ or $KEY_R \leq KEY_F$

Where KEY_R is the key requested and KEY_F is the key found.

(14) If the proposed software contains any system limitations such as number of files per disk drive, maximum file size, maximum record size, and so on, such specifications must be stated in the proposal.

(15) It is required that the operating system be able to distinguish between system software activity and user application software activity so that the system can protect itself from user errors.

(16) It is highly desirable that the system be capable of accepting a "down-line-load" from a remote host system. Bidders shall provide a comprehensive description of the methodology employed.

(17) Vendor should describe availability and cost of source code for operating system, language processors, and all other vendor-supplied software.

b. *Language Processors*

(1) Describe "high-level" multi-user language capability as applicable to the development of application programs. Specify the extent of multiprogramming, multitasking, and re-entrancy of code generated by available compilers. Highly desirable high-level languages include COBOL, FORTRAN, RPG, BASIC, ALGOL, and PL/1.

(2) Specify and describe the user environment in which application programs would be developed, tested, and implemented. Include a scenario of the coding, integration, and testing process.

(3) Describe and provide examples of accomplishing data storage and retrieval in a high-level language—particularly data with alphanumeric "keys" of at least 25 characters in length.

(4) Describe the available MACRO assembler, if any.

c. *Query and Source Data Entry Package*

(1) A generalized package of this type is not mandatory. If the vendor wishes to describe a supplementary package which would be useful to LC, they may do so.

d. *Sort/Merge and General Utilities*

(1) Provide a "sort/merge" capability and describe typical performance results. State the time required to sort from 1,000 to 20,000 records in 1,000 record increments, listing the system, disk, and core resources required, assuming no other active tasks, a 12-character sort key, and a 200-character record. It is desirable that this sort/merge be callable from application programs in either high-level language or assembly language.

(2) Describe the system's ability to perform general utility functions and the environment in which they are performed (i.e., under language interpreter or operating system control).

(3) Describe the software for performing disk pack backup copies and typical times involved.

e. *Communications*

(1) Describe software for emulating/simulating a 2780/HASP/JES/RES IBM compatible work station for 370 batch communications.

(2) Describe the capability (if any) for a proposed system to communicate with another proposed system.

f. *Data Base Management System* (Optional—Desired)

(1) General

It is desired that the DBMS relieve the application programmer of concern for the overall organization, structure and maintenance of the data base. The DBMS should insulate the application program from equipment differences among storage devices.

(2) Host Languages

The DBMS system should provide a high-level language interface capability to support application programs development. The DBMS should include the capability for such application programs to utilize all of the DBMS functions either through language extensions or supported call statements.

(3) Processing Modes

The DBMS should have the capability to support both batch and interactive modes of processing in a multi-user environment; that is, multiple terminals/programs should be able to update/retrieve from the same data base concurrently.

(4) Data Definition

There should be a facility in the DBMS to support the definition of data to the application program. Included in the definition capability should be features such as the following:

(a) The definition of data bases and keys.

(b) The assignment of symbolic names to data bases, data elements, and groups of data elements.

(c) Characteristics of each data element such as size, number of occurrences, and type, such as alpha or numeric.

(d) A listing of data definitions with diagnostics.

(5) Data Base Recovery

The capability to recover the entire data base in a timely manner is imperative. In this respect, several requirements are specified below.

(a) Ability to copy the entire data base or specified portions onto an auxiliary storage media upon command.

(b) Ability to restore the data base from a previously generated copy along with all associated indices, pointers, and directories.

(6) General Capabilities Desired

The following capabilities are desirable and should be available to users through the query language and directly from a program written in the proposed host languages.

(a) Efficient space allocation and de-allocation.

(b) Variable length records via repeating groups or attached members.

(c) Multiple indexes on a single file with duplicate keys allowed.

(d) Randomized and tree index structures.

(e) Data dictionary.

(f) Minimal record and file size limitations.

(g) Ability to insert, delete and update records in a data base without necessitating its recreation.

(h) Ability for multiple users in all processing modes to concurrently access a common data base.

(i) Specify all utilities required to maintain the data base include vendor supplied or customer required.

(j) The ability to create and retrieve on sub-indexes is desirable.

g. *Word Processing Subsystem* (desired)

(1) General

It is desired that a software system which would facilitate word processing applications be described if available. This system should be oriented around a full page (58 lines of 80 characters or standard $8\frac{1}{2} \times 11$) CRT. The emphasis is placed on ease of use and ease of training of relatively unskilled typists. If the vendor does not have software of this type, LC will entertain recommendations as to where it might be obtained.

(2) Software

The software would be preferred in a high-level language to facilitate easy support. It will be required that the source code for the subsystem be supplied with delivery of the system. Furthermore it is required that a full, detailed configuration and operating system environment description be provided as part of the proposal with a general description as to whether it is a stand alone system or concurrent running with other application programs.

(3) The following word processing functions are desired.

WORD PROCESSING MINIMUM CAPABILITIES

1. Insert character
2. Insert line
3. Delete character
4. Delete line
5. "Edit" or "Break" for variable length input of additional text.
6. Erase (Deletion of character that leaves a space).
7. Move Character
8. Move line
9. Move paragraph
10. Move page
11. Must be able to print and edit or keyboard simultaneously.
12. Local storage of minimum of 30 pages of text (1 page = 200 characters).
13. Keyboard commands and use of system training not to exceed 20 hours for full capability. Employee should be able to be completely productive (maximum productivity) by end of 80 hours (includes training time).
14. Printer must be capable of printing total screen text (58 lines × 120 characters).
15. Should have global search and replace
16. Automatic pagination
17. Ease of handling footnotes
18. Decimal justification
19. Diacritics

(4) File handling capabilities

In addition to the word processing requirements it is required that files or documents be accessed via keyed retrieval methods as described in section 3.a.13. Provisions must be made such that several individuals can be working on the same document concurrently and have the system reassemble the document into proper sequential order.

(5) The system should also be capable of communicating with the LC mainframe CPU, IBM 370/158 with appropriate communication link control as described in section 3.e.

h. *General Requirements*

(1) The equipment design shall provide for maximum useful service life under twenty-four hour/day, seven day/week operation as a design goal, obsolescence not withstanding. Useful service is defined as the continued ability to meet the performance reliability and maintainability specifications herein, assuming that preventive maintenance in accordance with the vendor's peroposal is practiced. Vendor shall state minimum and maximum useful service life and warranty. The equipment will require *no* special facility to be constructed. The operating environment shall be that of normal office conditions.

(2) The equipment shall operate and maintain specified performance from a single phase power source of 115V+- 10%, 60 cycles +- 1 cycle, or a three phase, four wire power source of 115/208 V +- 10%, 60 cycle +- 1%.

(3) The vendor shall insure that all equipment will operate as specified in the probable internal and external electromagnetic and electrostatic environments without loss in performance and without, through the electromagnetic energy it generates, causing other equipment to malfunction. Designed suppression of radiated and constructed interference shall permit the equipment to operate without error from incoming interference sources such as florescent lighting, power lines, general purpose high-speed digital computers and their auxiliary equipment. It shall be the vendor's responsibility to inspect the site and review equipment installation plans with LC.

(4) Electromagnetic or other radiation hazards potentially harmful to operating or maintenance personnel shall be constrained within the limits established by the National Council on Radiation Protection and Measurements.

(5) The equipment shall have UL approval and perform as specified while operating under the following conditions:

- Ambient Temperature Range. 50 to 90 degrees F provides there is no condensation.
- Relative Humidity. 10% to 90% within the ambient temperature range.
- Other Atmospheric Conditions. Any probable combination of smoke, ozone, fine dust, or any other atmospheric conditions which are likely to be encountered in an office building.

(6) The vendor will provide detailed specifications of the proposed system as an entity and define characteristics for system integrity. These shall include, but not be limited to:

- Detailed listing of system components.
- Dimensions of all items of equipment and proposed installation layout.
- Power supply requirements.
- Overload protection.
- Required system operating environment, particularly cooling and electrical.
- Modular growth characteristics and estimated useful life
- Detailed description of the technical characteristics of each component including MTBF (Mean Time Between Failure), MTTR (Mean Time to Repair), and MTBI (Mean Time Between Interrupt — meaning abnormal termination of operating system software.) The vendor must meet or exceed the following figures or explain to the satisfaction of the LC why his figures should be accepted as a reasonable alternative:
    - MTBF: See paragraph i.3. which follows
    - MTTR: See paragraph i.4. which follows
    - MTBI: See paragraph i.5. which follows
- Workload processing capability.
- Operational safeguards.
- Software interfaces.
- Hardware interfaces.
- Previous operational applications.
- Performance expectation (Throughput, etc.).

(7) Specify the expandability or maximum capability of the system for memory, disk storage, CRTs, and printers.

(8) Specify the source of all hardware and software being proprosed which has not been directly produced or manufactured by the vendor.

(9) Provide the name, title, address, and telephone number of the vendor's representative who bears sole responsibility for this proposal and ensuing contract. This representative would be contacted only in the event of unusual circumstances; day-to-day situations would be handled at a lower organizational level.

i. *Reliability*

Performance capability of the system will be based upon calculations from demonstrated field experience. Definitions and establishment of the quantitative criteria follow:

(1) A system is the basic configuration of CPU's memory, DISKS, and tapes (if the tape option is exercised) and will *not* include any of the terminals supported by the system, telephone lines, cables, or utility power.

(2) *Failure* : A failure is defined as one or more of the following:

(a) Any component failure in a CPU causing the system to cease functioning.

(b) Failure of the internal system power supplies to deliver the correct voltage

(c) Failure of any component in the memory which disables usage

(d) Failure of any component in the controller (if one is used) controlling the two synchronous channels

(e) Failure of both of the synchronous channels

(f) Failure of any component in the controller (if used) controlling the asynchronous channels.

(g) Failure of more than ten percent of the asynchronous channels.

(h) The system fails to operate within the specified environmental limits.

(3) *MTBF* : The demonstrated mean time between failure for a population of systems shall be 12,000 hours as a goal. The goal should be realized in a one year time period. The LC will evaluate at the end of this time period whether the goal was met and the suitability of the proposed system.

The MTBF shall be calculated as follows:

The system will be utilized over a 12 hour period daily. Failures occurring outside this 12 hour period will not be charged against the system provided they have been repaired before start up time the following day. It is desired that an unattended system be able to report itself "in trouble" to the main 370/158 at the Library of Congress so that service personnel may be dispatched.

Overall system reliability may be accomplished by one or more of the following suggested approaches:

(a) Dynamic reconfiguration which is achieved by online test and diagnostic capability coupled with sufficient hardware sophistication for the system to realize a module is in trouble, configure the module out, report the failure, and not interrupt operation. *This is the desired approach.*

(b) Manual reconfiguration which may be accomplished by a user or by an operator at a central terminal or at the 370/158 site. A short interruption occurs.

(4) *MTTR:* Mean time to repair is desired to be less than 30 minutes (after the field engineer has arrived at the site). The proposal shall identify all evidence leading to this conclusion.

(5) *MTBI:* Mean time between interruptions shall apply to interruptions caused by either the operational system software or the system hardware. It is expected that interruptions will occur more frequently immediately following installation of the system, but will be expected to improve once the burn in period has elapsed. MTBI is intended to cover those interruptions which cannot be traced to either system software or hardware as well as those that can be and is included to encourage the offerer to quote tested stable systems as far as practical. The following MTBI figures are desired:

(a) For the first month—100 hours

(b) For the next two months—500 hours

(c) For the next three months—1,000 hours

(d) For the remainder of the time—during each working day of 12 hours or less the reliability shall be 0.999 equivalent to one tenth or one percent probability of failure, equivalent to a mission MTBI of 12,000 hours.

(6) *Design Life:* The design life of the equipment is to be 10 years at 24 hours per day operation.

j. *Design Approach*

We require that the reader provide us with full details of the design approach bid, including the architecture and logic for achieving the required reliability and/or failure tolerance. We will entertain all sound design concepts that can achieve the desired reliability including n-processor approaches.

☆ U.S. GOVERNMENT PRINTING OFFICE : 1978O—259-882

TABLE 17—Alternative 1

Design Characteristics	Hardware/Software Impacts	Library System Specifications	Minimum Class of Computer
Means of Inputting One-way.	I/O Device: input only. Ex.: keyboard, card reader, paper tape reader.	Keypunch machine at each library. Punch card reader for computer configuration.	
Types of Output Products Hardcopy: Special forms and multiple copies.	I/O Device: printer with special paper capabilities–probably an impact type to handle multiple copies.	Impact printer, probably a line printer for speed in printing 15 copies (i.e., three or four runs).	
File Structure and Size Structure: Sequential.	Mass Storage Device: any type can handle sequential. Ex.: punch cards, paper tape, cassette tape, magnetic tape, diskette, or disk.	Open (Class III dictates no disk).	
Applications Characteristics Sorting: Alphabetic.	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.	Optional (Class III dictates magnetic tape or diskette (if capacity is large enough).	III

TABLE 18—Alternative 2

Design Characteristics	Hardware/Software Impacts	Library System Specifications	Minimum Class of Computer
Means of Inputting One-way. Outside source: Offline machine-readable form.	I/O Device: key-to-disk station or intelligent terminal. System Software: floppy disk operating system.	Key-to-disk station at each library. Floppy disk drive for computer configuration.	
Type of Output Products Hardcopy: Special forms.	I/O Device: printer with special forms capability	Printer, line or character.	
Machine-readable output form (offline).	I/O Device: same medium as input station, i.e., floppy disk. System Software: floppy disk operating system.		
File Structure and Size Structure: Can be either sequential or direct access.	Mass Storage Device: any type can handle. Ex.: cassette tape, magnetic tape, diskette, or disk. Size of file is the controlling variable.	Open (Class III dictates no disk).	
Applications Characteristics Sorting: Alphabetic.	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.	Optional (Class III dictates magnetic tape or diskette if capacity is sufficient).	III

TABLE 19—Alternative 3

Design Characteristics	Hardware/Software Impacts	Library System Specifications	Minimum Class of Computer
Means of Inputting			
Conversational.	I/O Device: two-way (output or response capability).		
Location of input stations.	Communications Equipment: hardwire or telecommunication line.	Due to distances of the libraries, telecommunications lines and equipment must be used.	IV
Multiple online users.	I/O Device: two-way (conversational capability). Communications Equipment: telecommunications lines or hardware lines. System Software: must handle telecommunications functions if that method is used.	Terminal must have modem.	
Type of Output Products			
Hardcopy: Special forms	I/O Device: printer with special forms capability.	Printer, line or character.	
File Structure and Size			
Structure: Direct access	Mass Storage Device: disk device (diskette, fixed-head disk or movable-head disk). System Software: disk operating system.	Disk system.	
Application Characteristics			
Sorting: Alphabetic	Mass Storage Device: large working space required and access to several areas at one time. Tape system will require three drives. Disk system could have one large disk.		
Remote Access	Communications Equipment: hardwire lines or telecommunications lines and modem. Communications Controller: may require a processor.	Telecommunications system.	

It is apparent that not every design characteristic pertains to every application and that not every system requirement is translated into a design characteristic. However, in both cases each must be considered, and an individual judgment must be made as to relevance. For example, the size of the file in this case has no impact on the design. The 4,000 volumes would be represented by 1.2 million characters (300 characters per record). Not all would be on the file at one time (only the titles being ordered during the biweekly cycle). There is no file size limitation for punch cards, paper tape, or magnetic tape as mass storage techniques. There is a size limit (capacity) for floppy disks, but a single side holds 250,000 to 300,000 characters, which is large enough for this application.

In determining the lowest class of minicomputer system required to handle the alternative design, there are triggers that eliminate lower classes or dictate a minimum level. For example, Alternative One (Table 17) does not require a Class III system until the design characteristic of sorting is considered. Class III is the lowest level that can handle sorting. Alternative Two (Table 18) follows the same pattern. Alternative Three (Table 19) requires an online interactive system with telecommunications capability. The lowest level that can handle this requirement is Class IV.

The Analysis

The design model makes it apparent that the cruder, simpler Alternative One will not save any money by using a lower class of minicomputer. Both Alternatives One and Two require a Class III system as a minimum. The cost differences will be in the cost of input devices, the cost of the line printer, and the processing time and cost of paper supplies that production of 15 printouts will require. Class III computers can handle communications, so it is feasible to investigate connecting each input station to the computer to transmit data in a batch mode. Turnaround time will decrease.

CATALOGING

Markuson and her collaborators state that there are three distinct types of catalog systems: (1) listing systems, which mainly prepare output products such as catalog cards, book catalogs, and labels; (2) control systems, which support catalog operations in such areas as thesaurus control, shelflist inventory control, and file maintenance; and (3) search systems, which "provide mechanisms for accessing the catalog data by a number of search elements."[26] Markuson's cataloging functions are outlined in the following list.[27]

1. Establishment and Surveillance of Catalog Policies and Procedures
   - Policy development
   - Maintenance of procedure manuals
   - User feedback analysis
   - Performance analysis
   - Interlibrary cooperation
2. Establishment and Maintenance of Local Authority Lists or Adoption of Standard Lists
   - Name authority files
   - Subject authority lists; thesaurus
   - Other authority files
   - Classification schedules
   - Filing rules
   - Descriptive cataloging rules
3. Materials Analysis
   - Descriptive analysis
   - Author entry establishment
   - Subject analysis and indexing
   - Classification and reclassification
   - Abstracting
   - Preparation of initial catalog record
   - Revision and correction of initial record
4. File Input and Maintenance
   - Record input preparation and revision
   - Filing
   - Cross-reference control
   - Error correction
   - Transaction control; additions and deletions
5. Materials Handling
   - Sorting and preliminary control
   - Distribution to catalogers
   - Arrearage control
   - Pasting and labeling
   - Routing
6. Inventory Control
   - Establish shelflist record
   - Added copy control
   - Added volume control
   - Recataloging and reclassification control
   - Inventory statistics maintenance and analysis
7. Reference and Retrieval
   - File searching
   - Retrieval of item in process
   - File inquiry assistance

[26] Markuson et al., *Guidelines for Library Automation*, p. 73.
[27] Ibid., pp. 76–77.

8. Output Generation, Dissemination and Reporting
   - Report generation
   - Preparation of printed cards, worksheets, etc.
   - Preparation of printed book catalogs
   - Preparation of printed labels
   - Preparation of printed/punched book cards
   - Preparation of printed lists
   - Preparation of indexes
   - Dissemination of records
   - Union list reporting
9. Processing Catalog Records from Outside Sources
   - Ordering catalog records
   - Organization and dissemination of hardcopy records for cataloging
   - Processing, and maintenance of machine-readable records
   - Modification of nonlocal records
   - Selective dissemination of records

Establishment and surveillance of catalog policies and procedures is mainly an intellectual, judgmental function. Information to support decisionmaking can be provided by other automated functions, and statistical analyses and modeling can be performed by computer to support the user feedback and performance analyses activities. In addition, automated text processing can be used to maintain procedures manuals.

Establishment and maintenance of local authority lists or adoption of standard lists is both an intellectual and a clerical area. The maintenance of authority lists is essentially clerical, with file maintenance forming its major part. Automated systems have "maintained" and generated local lists for some time. Editing, updating, and control of the files, however, were done by human beings, who handled the files manually. Computer generation of authority lists has been tried (using a keyword approach), but without much success. More standard lists are now available for purchase in machine-readable form; such a list can be the basis of the local list. Filing rules for computers have been compiled and automated catalog filing has been performed for some time, but the complexity of the rules has varied among systems. Some of the more complicated schemes require human editing and human creation of sort keys, which the computer then manipulates, rather than using computer-generated sort keys based on program parameters. Computer support in this area can produce greater clerical efficiency, but the intellectual basis for authority work must still reside mainly with human beings.

Materials analysis is almost entirely intellectual in nature, and in terms of creation of original cataloging entries no major automation effort has progressed past the experimental or research stage. Initial catalog records have been computer-built from an automated acquisitions file, but the initial identification of the descriptive elements was human-generated in the acquisitions phase. The support of automated authority lists can make materials analysis more efficient and consistent, but it can do little more.

Automation can be used to identify items that already have a catalog entry established by either the Library of Congress or another library. Searching the MARC data base or a larger network data base is possible through an automated system. If this search is made, then the human can analyze the material (book in hand) in terms of the entry and accept, reject, or modify it as necessary. This procedure has significantly reduced the number of items that require original cataloging and greatly relieved the intellectual burden of the cataloging department of individual libraries. Programs for reclassifying from one scheme to another (e.g., from Dewey to L.C.) can be written, but the results must still undergo heavy human scrutiny and revision.

File input and maintenance is a natural area for automation. The nature and degree of file automation can vary from library to library, however. If the library catalog file is the card catalog, the file input is in the form of catalog cards, which can be formated, printed, overtyped, and sorted for filing by an automated system. The actual filing and maintenance would have to be done by humans. If the file were to be a computer-based file for producing book catalogs or COM catalogs, or for online searching, this file input and maintenance and its automated system would have to be more extensive and elaborate in nature. The catalog entry, once established, would have to be converted to machine-readable form. This conversion entails explicitly identifying separate data elements and their natures, so that the program can manipulate each as required. The MARC format provides a framework for explicitly identifying these elements, but the editing is usually done by people, not machines. The Library of Congress has developed a format recognition program that analyzes a catalog entry and generates MARC tags and fields with an accuracy rate of about 75 percent. Once the editing is performed, the source record must be converted into a machine record and read into the system. Some automated systems generate cross-references by com-

paring the subject entries for the local catalog to a standard authority list, such as the eighth edition of the Library of Congress subject headings list.

Materials handling is basically a manual activity, but automation can be used to control arrearage or backlogged items, items in process, and routing of items.

Inventory control can be fully controlled, or at least supported, by automation. The degree of control depends partly on how much retrospective conversion of the card catalog to machine-readable form has been undertaken. If automation efforts have been limited to new titles only, there will not be enough basis for complete control. An effort will have to be made to create a file especially for inventory control. It may be possible to convert the shelflist or use a related file, such as an existing circulation system file. Some libraries approach retrospective conversion on a need basis; the added copy or added volume control system triggers the establishment of a machine-readable record in the computer file. The degree of sophistication of the automated statistical data and analyses also depends on how much of the entire catalog is in machine-readable form.

Reference and retrieval can be automated to a certain extent. Once a computer file is created, automated search and retrieval can be performed on it. Human beings, in some circumstances can initiate it, and in other situations program control can. For example, an acquisitions program could search the catalog holdings file automatically to determine whether a purchase request is a duplicate copy.

Output generation, dissemination, and reporting (the preparation of cataloging output products — cards, book catalogs, COM catalogs, labels, book pockets, bibliographies, and indexes) is well suited to automation. However, automation depends, of course, on the degree of automation of other cataloging functions, e.g., amount of retrospective cataloging converted, tag structure used, etc. The idea is to key the data once and use it over and over in different forms, formats, and permutations.

Processing catalog records from outside sources becomes more and more practical as the use of catalog records in machine-readable form becomes more widespread. These are available through commercial sources and networks. The MARC tape distribution service has made almost 1 million cataloging records available to libraries and vendors, thus reducing the need for much duplicated effort.

Typical cataloging problems that can be solved wholly or in part by a minicomputer system include

- Maintenance of a name authority file
- Maintenance of a subject authority file and cross references
- Maintenance of a thesaurus
- Maintenance of a series authority file
- Efficient means to produce overtyped card sets
- Production of book or COM catalogs
- Maintenance and control of a catalog for a special documents collection
- Control of added copy and added volume routines
- Preparation of precataloging card sets and processing kits
- Control of items in process
- Maintenance of a union catalog of several collections
- Preparation of special bibliographies on request
- Preparation of permutated indexes.

SERIALS

Serials, as an operational area of a library, are difficult to pin down. The processes involved are basically acquisitions and cataloging and in some libraries are incorporated in the regular flow for book materials. Even what is defined as a serial can vary: periodicals, newspapers, technical reports, Government documents, annuals, handbooks, and other works issued in frequent editions, sets in progress, services, and monographic series.[28] Markuson, et al., defined two main types of serial systems: (1) listing that provides "access to, and control of, certain facets of the serial operation," and (2) check-in control that provides "mechanisms for the control of the receipt, recording, and routing of incoming serial issues."[29] Her list of serial functions follows.[30]

1. Establishment and Surveillance of Policies and Procedures
   Policy development
   Maintenance of procedure manuals
   User feedback analysis
   Performance analysis
   Collection analysis
   Interlibrary cooperation
2. Subscription Control

[28] Ibid., p. 110.
[29] Ibid., p. 109.
[30] Ibid., pp. 113–4.

Review of new order requests and renewal requests
Determination of procurement procedures
Establishment and maintenance of subscription control files
Preparation of subscription renewal approval lists
Order preparation
Fund accounting
Vendor and source file maintenance

3. Establishment and Maintenance of Bibliographic File Control
   Catalog new serials, recatalog old titles
   Prepare serial record entry
   Provide cross-reference controls
   Update serial holdings
   Transaction control: additions, changes, deletions
4. Recording Incoming Receipts
   Sorting and assignment of incoming issues
   Bibliographic identification
   Posting to control file
   Marking and routing issues
   Recording changes in bibliographic or control information for file updating
   Claiming
5. Materials Handling and Collection Control
   Sorting and shelving issues
   Servicing request for serial issues
   Routing and circulation control
   Storage of title pages, indexes, etc.
   Establishment and maintenance of binding control file
   Missing issues control
   Preparation of want lists to complete holdings
6. Output Generation, Dissemination, and Reporting
   Preparation of serial holdings lists
   Preparation of accessions lists and bibliographies
   Union list reporting and/or printing
   Printing order forms and subscription renewal lists
   Print claim notices
   Print binding notices
   Prepare serial check-in forms or arrival cards
7. Reference and Retrieval
   Processing bibliographic verification inquiries
   Processing holdings and assigned location inquiries
   Retrieval of serial issue from processing flow
8. Processing Nonlocal Records
   Union list maintenance and publication
   Selection and dissemination uses
   Purchasing and bibliographic control

Establishment and surveillance of policies and procedures, like the other areas, involves mainly intellectual effort and can be only supported or aided by automation. The analyses needed in this area can be supported by automation more fully if the other functions are automated and the data can be collected by machine.

Subscription control, like acquisitions, includes both intellectual and clerical activities. Although selection is a human decision, the review of renewal requests can be aided by a computer alert that signals when subscription renewal is imminent. In addition, analysis of previous subscriptions can provide means of projecting subscription prices. Order preparation and fund accounting are clerical in nature and easily automated, as is the vendor and source file.

Establishment and maintenance of bibliographic file control begins with establishing and structuring the bibliographic elements for a serial according to standard rules. This activity is intellectual and must be done by a human being. Each entry then must be coded and converted into machine-readable form for further manipulation. The nature of periodicals is such that once an entry is established, it is subject to many changes, for example, title, frequency, and the corporate name of the issuing agency. The actual holdings of the periodicals are in a constant state of flux, the current status of which must be maintained. These changes indicate the need for many cross-references. All of this maintenance and control can be greatly aided by automation.

Recording incoming receipts can be aided greatly by automation. Although the initial sorting and subsequent routing of incoming issues is a manual process, the remaining activities are clerical and can be automated — or, if not fully, at least the computer can provide support. The means of constantly capturing the data, updating the status of the file, and generating claims when needed are the key elements in an automated serials system.

Materials handling and collection control includes some manual activities, but these can be supported by automated clerical processes, as in control and maintenance of the various files and the generation of different lists.

Output generation, dissemination, and reporting can be fully automated. When the information has been captured in machine-readable form, computer-generated output is an efficient means of producing lists, forms, or notices. With an online computer system,

however, the need for some of the printed output may be eliminated.

Reference and retrieval can be eased by automation. The information in serials files must be accessible by the library staff at various stages of the work flow. Part of the information also is needed by the library public and must be made available in a format designed for public use. Due to the nature of serials, there are many potential access points for any entry, and the historical data for each serial can be significant. The value of automation is its ability to manipulate data over and over, in an efficient and economical way, in hardcopy or softcopy form.

Processing nonlocal records is a function that automation furthers, for example by producing union lists of serials from the collections of several libraries. The holdings and titles on the lists can be kept current with great ease and efficiency, and the production of the lists can be accomplished quickly and economically. The introduction of serial records distributed in MARC format by the Library of Congress and the new cooperative serials project CONSER have made more standard cataloging entries available for libraries and reduced the amount of coding and keying required to build a bibliographic file for serials.

A number of typical tasks that can be done by a minicomputer system are

- Controlling subscriptions: orders and fund control
- Maintaining and controlling a catalog of serial titles
- Preparing and controlling union lists of serials from several collections
- Controlling routing for new issues
- Controlling the finding of materials
- Controlling continuations
- Checking in new issues efficiently
- Efficiently handling claims of both titles and individual issues
- Maintaining and controlling information on where individual serials are indexed and abstracted.

CIRCULATION

Circulation systems vary not so much in type as in degree. Some maintain only transaction information — what is currently charged out — and some maintain files on all potential borrowers, all materials in the collection, and all current transactions. Some systems handle overdue notices, reserve books, and maintain hold files and a bad borrower file.

Markuson and her colleagues compiled the following list of functions of the circulation operation.[31]

1. Establishment and Surveillance of Policies and Procedures
   Policy development
   Maintenance of procedure manuals
   User feedback analysis
   Performance analysis
   Interlibrary cooperation
2. Authorized Borrower Control
   Borrower registration
   Borrower identification
   Special routines for exceptional borrowers
3. Charging Procedures
   Charging materials, books, serials, etc.
   Recording charge transaction
   Book reservation procedures
4. Discharging Procedures
   Discharging materials
   Recording discharge transaction
   Identification of reserved items
5. File Input and Maintenance (all files)
   Transaction record input — charges, discharges, etc.
   Borrower file input
   Transaction control, additions, deletions
   Error correction procedures
   Inventory control records
   Overdue and fine accounting
6. Overdue Control
   Identification of overdue items
   Receipt and control of overdues and fines
7. Interlibrary loan
   Monitoring of interlibrary loan requests — incoming
   Monitoring of interlibrary loan requests — outgoing
8. Output Generation, Dissemination, and Reporting
   Charge records
   Overdue notices
   Reserve notices
   Report generation
   Preparation of printed circulation and discharge lists
   Dissemination of records, reports, etc.
9. Reserve or Special Noncirculating Materials

[31] Ibid., pp. 130–1.

Establishment of control procedures
Maintenance of special transaction files for noncirculating and reserve materials
10. Reference Inquiry
Identification of items on loan
Identification of missing items
11. Materials Handling, Storage, and Maintenance of the Collection
Retrieval of requested items
Reshelving and maintenance of items
Routing of materials
Physical preservation of items
Inventory of collection
Purging of outdated and unwanted items
Preparation of materials for shipment

Establishment and surveillance of policies and procedures is mainly an intellectual activity. Automation can be used to support the decisionmaking with statistics gathered and analyses performed.

Authorized borrower control is a candidate for complete automation. Borrower registration can involve merely individual borrowers providing information for the file. However, in many special libraries the borrowers' file can be taken from an existing file of agency employees. In most cases a control number, such as the social security number, is assigned. Often systems use an identifying badge or card with the number in machine-readable form to provide the means of input. If special classes of borrowers exist, these can be handled via algorithms.

Charging procedures entail gathering the necessary information to record an item as in circulation. Information on the book, the borrower, and the details of the loan itself (charge date, due date, branch or location, etc.) are generally needed. The ease with which this information can be gathered is critical. Book reservations procedures can be automated so that a book cannot be checked out except by the person who is next on the "hold" list. A notice to this next person informing him of the availability of the book can also be generated automatically.

Discharging procedures are the reverse of the charging procedures and usually involve gathering statistics on use for future analyses.

File input and maintenance is critical to all files in the system, although they can vary with different system designs. The major factor in this subfunction is the efficiency with which the data can be captured and the records kept current (updated).

Overdue control is eased by automation. A system for automated control of overdue materials, generation of overdue notices, and computation of fines is simple if the original transactions are in machine-readable form. (Interlibrary loans will be discussed as a separate operation.)

Output generation, dissemination, and reporting includes a variety of functions. The output products that can be computer-generated depend on which functions are automated. For online systems many of the printed products are no longer necessary.

Collections of reserve or special noncirculating materials are kept by some libraries under special loan procedures, such as short-term loans for several hours or unlimited loans for indefinite time periods. Once algorithms are defined, the procedures can be automated.

Reference inquiry to circulation must be accommodated. Both library staff and the users need to access the transaction file to ascertain the status of specific items or of particular users' total transactions.

Materials handling, storage, and maintenance of the collection consists mainly of manual activities. Automation is used only in a support or utility role. A minicomputer can be used to support any or all of the phases of a circulation system as discussed and its real value is in making an online system viable.

INTERLIBRARY LOANS

Interlibrary loan processes can be included in the circulation operation or set aside as a separate operation. The process is divided into two main functions, incoming and outgoing interlibrary loan requests.

Hayes and Becker described the interlibrary loan functions as follows.[32]

I. Borrowing
 A. Making request
  1. Assistance to patrons
  2. Determining location, verifying
  3. Completing form, filing
  4. Mailing
 B. Receiving item
  1. Receiving and unwrapping
  2. Checking records
  3. Notifying patron
 C. Payment
  1. Keeping records
  2. Making payment, mailing
 D. Returning item

[32] Hayes and Becker, *Handbook of Data Processing for Libraries,* pp. 574–5.

however, the need for some of the printed output may be eliminated.

Reference and retrieval can be eased by automation. The information in serials files must be accessible by the library staff at various stages of the work flow. Part of the information also is needed by the library public and must be made available in a format designed for public use. Due to the nature of serials, there are many potential access points for any entry, and the historical data for each serial can be significant. The value of automation is its ability to manipulate data over and over, in an efficient and economical way, in hardcopy or softcopy form.

Reference inquiry to circulation must be accommodated. Both library staff and the users need to access the transaction file to ascertain the status of specific items or of particular users' total transactions.

Materials handling, storage, and maintenance of the collection consists mainly of manual activities. Automation is used only in a support or utility role. A minicomputer can be used to support any or all of the phases of a circulation system as discussed and its real value is in making an online system viable.

INTERLIBRARY LOANS

Interlibrary loan processes can be included in the circulation operation or set aside as a separate operation. The process is divided into two main functions, incoming and outgoing interlibrary loan requests.

Hayes and Becker described the interlibrary loan functions as follows.[32]

I. Borrowing
 A. Making request
  1. Assistance to patrons
  2. Determining location, verifying
  3. Completing form, filing
  4. Mailing
 B. Receiving item
  1. Receiving and unwrapping
  2. Checking records
  3. Notifying patron
 C. Payment
  1. Keeping records
  2. Making payment, mailing
 D. Returning item

[32] Hayes and Becker, *Handbook of Data Processing for Libraries*, pp. 574–5.

1. Changing records
2. Wrapping and sending

II. Lending
A. Receiving request
1. Receiving and verifying
2. Checking catalog, locating
3. Searching shelves, pick-up
4. Keeping records, check-out

B. Photocopying
1. Checking pages requested
2. Sending to photocopy
3. Copying
4. Keeping records
5. Preparing, logging invoices, filing
6. Processing payment upon receipt

C. Sending
1. Wrapping
2. Distributing or mailing

D. Followup
1. Sending overdue notices
2. Keeping records

E. Returned items
1. Unwrapping and inspecting
2. Changing records
3. Discharging
4. Reshelving

User interface, establishing entries, searching and locating sources or items, and checking materials are all intellectual activities. Searching and locating sources can be automated if there is a data base of holdings accessible to outside sources. For example, an online cataloging or circulation data base that can be accessed from external terminals could be used to search and locate sources. The other intellectual activities do not lend themselves to automation. The manual activities — handling the material, shelving or pulling, wrapping or unwrapping, and photocopying — also cannot be automated. The rest of the functions are mainly clerical or control activities and can be automated.

The interlibrary loan tasks that can be supported by minicomputers include

- Preparation of request forms and control of items in the borrowed file
- Maintenance of a calendar for scheduling material returns
- Maintenance and control of an overdue system
- Maintenance and control of an items-loaned file
- Control of a borrowers' file and/or a source (supplier) file.

[33] Markuson et al., *Guidelines for Library Automation*, pp. 139–40.

REFERENCE AND INFORMATION SERVICES

The reference function represents interaction of the library user with the library representative. This representative can be a human (a member of the library staff) or a tool (the library catalog, an index, or a specific book), that meets the user's need to locate the information desired. Because technical processes provide the materials and means for serving the user, most of the tools used for reference are products of the technical services operations and systems.

Markuson compiled the following list of nine reference and bibliographic functions.[33]

1. Establishment and Surveillance of Policies and Procedures
   Policy development
   Maintenance of procedure manuals
   User feedback analysis
   Performance analysis
   Interlibrary cooperation
2. Development and Maintenance of Reference Sources
   Evaluation and selection of hardcopy reference materials
   Evaluation and selection of machine-readable reference materials
   Development of specifications for handling machine-readable reference materials
3. Identification of Relevant Outside Reference Sources
   Printed material sources
   Machine-readable bibliographic sources
   Machine-readable data-base sources
   Organizational and people sources
   Establishment of procedures for utilization of outside sources
4. Search and Retrieval
   Initial screen and/or referral
   Question negotiation and analysis
   Conversion of question to appropriate terminology
   Formulation of search strategy
   Conduct of search
   Evaluation of search
   Maintenance of library and user profiles
5. Preparation of Bibliographies

Definition of scope and type of bibliography
Screening of potentially relevant items
Preparation of bibliographic entry including abstract and annotation as required
Preparation of final copy
Duplication and dissemination

6. Requests for Photoduplication
Screening requests
Duplication
Distribution of photocopies
Accounting control
7. Preparation of Translations
Identification of language skills available within library or appropriate affiliated group
Identification of other sources of translation services
Screening translation requests
Preparation and presentation of translation
Accounting control
8. Establishment and Maintenance of Special Materials
Agency archival files
Records of local search results
Clipping and pamphlet files
Personnel skills inventories
9. Materials Handling
Maintenance of reference collection
Handling of items retrieved from other collections
Physical preparation and filing of special materials

Establishment and surveillance of policies and procedures is an intellectual activity, and automation can only support it, mainly by analyses of performance and user feedback. If formal survey techniques are used to gain user feedback, the necessary statistical analyses can be performed by an automated system.

Development and maintenance of reference sources is an intellectual activity that must be performed by human beings but is involved with automated efforts or products. Actual use of the machine-readable materials may be required for testing purposes.

Although *identification of relevant outside reference sources* is an intellectual activity, implementation of the machine-readable sources requires establishing an automated system or installing an existing system.

Search and retrieval can be performed manually on output products, such as card catalogs, book catalogs, or special bibliographies, or it can be done online at a terminal. In either case, the access points and the way the information will be approached must be determined in advance. The actual queries will depend on the search techniques chosen. (Is free text searching possible? Is Boolean logic searching available? Are predetermined descriptors required? Is a permutation technique appropriate?) Library and user profiles can be used for an automated SDI system if a machine-readable data base is available for searching.

Preparation of bibliographies can be automated. Computer-generated bibliographies can be produced from machine-readable data bases if the records are structured properly. For example, using the fixed-field data in the MARC II format, bibliographies could be compiled based on parameters dealing with language, country of origin, form of contents (yearbook, directory, etc.), types of illustrations present, year published, and so on. Current awareness lists and SDI lists based on profiles also can be considered bibliographies and can be computer-generated.

Requests for photoduplication are handled mainly by manual activity, but automation could be applied in accounting control.

Preparation of translations is an intellectual activity. The clerical functions of accounting control, preparation of orders or requests for translations, and maintenance of a file of sources of translation services can be automated.

Establishment and maintenance of special materials collections (such as photographs, clippings, internal research reports, commercial catalogs, and proposal/contract documents) can be controlled by automation. Some commercial systems provide for capture of source material on microforms and for search and retrieval of the data by minicomputer.

Materials handling is a manual activity that does not lend itself to automation.

Although most applications of minicomputers to reference and information services are approached through problems in the other operational areas, some needs can be mentioned:

- Public (user) access to the serials holdings file
- Public access to the thesaurus used
- Public access to materials in process
- Maintenance and control of special collections
- Maintenance, control, and access to microfiche documents collections
- Maintenance and control of files of human resources and their subject areas
- Maintenance and control of vertical files
- Access to commercially available online data bases of abstracts and indexes
- Maintenance and control of a current awareness and/or SDI system

- Production of special bibliographies on demand
- Performance of literature searches on demand.

ADMINISTRATION

Administrative functions vary according to the library's place in the parent organization's structure and the payroll, personnel, and budget control services provided by that organization. The functions of library administration are, in general, those present in any organization, and general business automation systems dealing with administrative activities should apply.[34]

Markuson's list of administrative functions follows.[35]

1. Establishment of Procedures vis-a-vis Parent Agency
   Legal requirements
   Funding, staffing, and operational policies
   Policies for joint sharing of facilities, e.g., computer equipment
   Reporting requirements and policies
   Identification of needed library services
   Establishment of interlibrary and interagency cooperation policies
   Establishment of contracting requirements
2. Personnel Procedures and Policies
   Personnel selection
   Establishment of personnel policies, records, benefits
   Formal and on-the-job training procedures
   Personnel and records management
3. Fund and Property Management
   Budget preparation and review, annual
   Budget preparation and review, long-range
   Budget allocation and surveillance
   Library fund accounting
   Cost analysis review
   Property inventory
4. Organization and Administration of Functional Operations
   Establishment of services to be performed
   Development and review of organization to perform services
   Development and review of administrative policies for each organizational unit
   Assignment of line and staff administrators
   Establishment of criteria for procedure manuals, forms, etc.
   Operations analysis review
5. Reporting
   Establishment of statistical and reporting requirements
   Preparation and review of annual reports
   Establishment of staff communication via meetings, newsletters, etc.
6. Coordination and Cooperative Efforts
   Establishment of local agency coordination policies
   Establishment of agency coordination policies
   Establishment of policies for coordination with other libraries and pertinent groups
   Assignment of staff to specific coordination functions
7. Long-Range Planning
   Monitor developments and needs in local and central agency
   Monitor developments in other libraries and relevant organizations
   Assign staff to planning tasks
   Prepare and periodically update long-range plans
8. Establishment of Systems Development and Evaluation Procedures
   Establish mechanisms for operational analysis
   Establish procedures for utilization of outside skills, e.g., contractors, staff sharing, etc.
   Establish policies for utilization of equipment, e.g., tele-typewriters, computers, etc.
   Establish review mechanism for operational changes
   Establish policies for cooperative planning, development, and implementation

Establishment of procedures vis-a-vis parent agency is an intellectual activity that must be performed by a human.

The major activities of *personnel procedures and policies* are intellectual, but records management can be automated.

Fund and property management consists mainly of intellectual activity, but property inventory control can be automated. The other activities of this function can be supported by automation in the form of statistical analyses, modeling, and simulation.[36]

[34] For a discussion of the automation of library administrative activities, see: Hayes and Becker's "Chapter Fourteen, Administrative Data Processing," *Handbook of Data Processing for Libraries*, pp. 383–414.

[35] Markuson et al., *Guidelines for Library Automation*, pp. 147–8.

[36] For a collection of essays on and a bibliography of library operations research, see: Peter Brophy, Michael K. Buckland, and Anthony Hindle, *Reader in Operations Research for Libraries* (Englewood, Colo.: Information Handling Services, Library and Education Division, 1976).

Organization and administration of functional operations is an intellectual area. Computer support is applicable to "operations analysis review."

Reporting can be supported by automation by using data gathered in other automated systems in the library. A word processing system can support preparation of reports.

Coordination and cooperative efforts is entirely intellectual in nature.

Long-range planning can be supported by automation, with either computer-generated data or computer analysis and modeling.

Establishment of systems development and evaluation procedures is an intellectual activity.

SUMMARY

The problems and solutions described in this chapter are merely representative of the tasks to which a minicomputer system could be applied in a Federal library. Individual libraries may have different needs that also can be served by minicomputers in the form of a standalone computer, a part of a network, or a local unit for a host computer. The number of minicomputer applications is limited only by the creativity of systems design teams. The possibilities are endless.

CHAPTER FIVE

SELECTION CRITERIA

As stated in the Introduction, Part II presents guidelines for selecting and implementing a minicomputer system. Part II begins with the assumption that a library has decided to use a minicomputer system. For those readers who are already familiar with minicomputers and who skipped Part I to begin this book at Part II, a suggestion is in order. The following guidelines are based on a design model described in Chapter Four and it may be of value to review this model.

FACTORS INFLUENCING THE DECISION

During systems analysis and design in Part I, various possibilities for solving problems or meeting needs were reviewed. The systems design document reviewed each one, provided the information on which the administrators made the decision, and contained all the details necessary to initiate the computer system.

How did they arrive at that position where they could make their decision? First, the problem or need was expressed in terms of specific goals and objectives. The existing system was analyzed, and system requirements for the new design were compiled. The design model was applied. That is, design characteristics pertinent to the system requirements were determined, and the hardware and software impacts for each were reviewed; the class (or classes) of computers was deduced for each of the choices; the systems document was prepared and the time for decisionmaking was at hand.

What factors were considered in the choice of alternatives? Some of the main factors in the design decisions were considered early in the phase of decisionmaking. The system requirements included the organizational and environmental impacts, as well as those of associated systems, and the constraints (physical, organizational, technical, contractual, and resources) that had to be taken into consideration.

The remaining factors deal with the various possible solutions, which had been shaped by the previous factors.

COMPARISON TO A MANUAL SYSTEM

Undoubtedly, in most problem areas a manual approach could be viable. A manual system and a minicomputer system, it must be stressed, really cannot be compared if the automated system is approached properly. The mini system should do more than the manual system but still allow all the necessary tasks to be performed. With any automated system the staff relief should be in the clerical ranks, as clerical tasks are the ones usually automated. There may be an increase in the duties and responsibilities of the paraprofessional or professional staff. Because information must be expressed explicitly for computer manipulation, the source data must be edited and coded before it is inputted. Higher level staff (if not to edit, at least to revise) is usually required. The entire operational area may feel the impact of automation.

An operation, to be automated, must be clearly structured, precisely defined, and tightly organized. Precedents and decisions must be recorded. Rules and authorities must be controlled and consistently applied. The degree of control may be much greater than in the manual system, and this may increase the work in the unit. For applications in which retrospective conversion may be appropriate, the decision whether to convert must be made. The file must be examined to determine how much must be converted (the file's volume) and how "clean" it is (how much editing must be done before converting).

COMPARISON TO A LARGE-SCALE SYSTEM

In comparing a minicomputer system to a large-scale system, the situation or environment must be established.[1] For example, comparison of costs or services must take into account whether the large-scale computer would be the library's own, the agency's (with or without charge-back fees), or that of a commercial service bureau or contractor. The main differences between large-scale computers and minicomputers were discussed in Chapter Two. Additional points should be made.

- An online interactive system on a mini may be cost-competitive with a large-scale batch system.
- A library gains more control over its destiny with its own mini but must take on the duties attendant in operation, maintenance, repair, etc.
- A large-scale computer may be best used along with, not instead of, a mini system. Very large requirements for sorting or printing can be performed on a large-scale computer, and this combination may be an alternative to consider.

SERVICE CONSIDERATIONS

Service considerations affecting alternative designs should be stated explicitly at the end of the system design phase. The choices should be more of style and degree than of services present or not. Impacts on users should be considered first, and then impacts on the staff. Time involved can be a variable, as can ease of operation or use. Undoubtedly tradeoffs will be made.

COST/BENEFIT ANALYSES

Cost analysis is part of systems design as outlined by Markuson, and the costs for each alternative should have been prepared. Markuson suggests that the analyses should include the following.[2]

1. Determine development costs for all aspects of the system including:
   - Manpower costs
     System design manpower
     Programming manpower
     Contractors and consultants
     Secretarial and clerical support
   - Communication costs
     Travel
     Telephone
   - Computer costs
     Computer time for program debugging and testing
     Computer time for data input and file building
   - File conversion
     Input preparation and editing
     Input operators
     Input equipment
   - Training
     Preparation of materials for staff training
     Special courses, etc. for project team
   - Other
     Expendable materials
     Space
2. Develop projections for operational costs:
   - Manpower for system operation and for system modification
   - Manpower for file input and maintenance
   - Equipment costs for input and computer processing
   - Expendable materials, e.g., printer forms, paper, labels, etc.
3. Compare operational costs for manual and computer system.
4. Prepare cost report

The costs alone are not enough. A cost/benefit analysis should be performed.[3] This judgment is difficult because so much of the "benefit" would be in

[1] Auerbach compares minicomputers with wired logic components, large-scale computers, and commercial time-sharing systems in terms of the five general application areas for minicomputers; *Auerbach on Minicomputers* (New York: Petrocelli Books, 1974), pp. 76–81. Hayes and Becker compare various system configurations for library applications; Robert M. Hayes and Joseph Becker, *Handbook of Data Processing for Libraries*, 2d ed. (Los Angeles: Melville Publishing Co., 1974), pp. 268–74. Davison raises three significant issues that must be considered when deciding between large-scale and minicomputers for libraries and Grosch lists seven questions to be answered; Wayne Davison, "Minicomputers and Library Automation: The Stanford Experience," in *Applications of Minicomputers to Library and Related Problems*, ed. F. Wilfrid Lancaster, papers presented at the 1974 Clinic on Library Applications of Data Processing, 28 April to 1 May 1974 (Urbana-Champaign, Ill.: University of Illinois, Graduate School of Library Science, 1974), pp. 93–95, and Audrey N. Grosch, "Minicomputer — Characteristics, Economics and Selection for an Integrated Library Management System," in *Applications of Minicomputers to Library and Related Problems*, ed. F. Wilfrid Lancaster, papers presented at the 1974 Clinic on Library Applications of Data Processing, 28 April to 1 May 1974 (Urbana-Champaign, Ill.: University of Illinois, Graduate School of Library Science, 1974), pp. 164–5.

[2] Barbara Evans Markuson et al., *Guidelines for Library Automation; A Handbook for Federal and Other Libraries* (Santa Monica, Calif.: System Development Corporation, 1972), p. 58.

[3] Kimber has a brief discussion on the economic aspects of automating, especially unit costs; R[ichard] T. Kimber, *Automation in Libraries*, 2d ed. (Oxford: Pergamon Press, 1974), pp. 23–26. Hayes and Becker have an entire chapter on cost accounting which is used to determine unit costs and other financial data for decisionmaking. They also have a chapter called "System Budgeting and Evaluation." This deals with criteria of evaluation, specifically cost/effectiveness (i.e., cost/benefit); see "Chapter 4, Cost Accounting in Libraries," and "Chapter 7, System Budgeting and Evaluation," *Handbook of Data Processing for Libraries*, pp. 102–21, 178–94. Becker and Hayes discuss the benefit aspect, i.e., defining the criteria of value; Joseph Becker and Robert M. Hayes, *Information Storage and Retrieval: Tools, Elements, Theories* (New York: John Wiley & Sons, 1963), pp. 238–56.

service, and library service has been notoriously difficult to quantify and evaluate. Swihart and Hefley call these "intangible costs" and express the problem this way:[4]

> Intangible costs must also be arrived at for every benefit claimed for a system. If service is to be improved, just how will it be improved, and specifically what value can be placed on it. Some library administrators will claim that they cannot estimate the value of faster service, more books, etc., but such judgments can be made with reasonable accuracy and when made, should be recorded in writing.

However it is accomplished, the point is that cost alone should not be the sole consideration. The benefits must be reviewed and considered in the decisionmaking process.

SELECTING THE SYSTEM

Once an alternative has been chosen, the next step is to decide how to proceed. There are three main choices: (1) The library and its agency can develop and implement the system, (2) a commercial contractor can be hired to develop and implement the system, or (3) a turnkey system can be purchased and implemented. The decision may take the form of a process of elimination. If there is no turnkey system available, the next question is whether the agency data processing unit can or will take on such a project. If not, there may be no recourse but to contract out the effort. Where options are available, the decision must be based on ability to meet the system requirements, costs involved, and time to complete.

Whichever method is followed, the steps involved are basically the same. Ollivier wrote that there were four distinct stages.[5]

> Design. Specifications.
> Solicitation. Problem description and specifications are sent as request for proposal (RFP) to a list of qualified vendors.
> Evaluation. Proposals submitted by vendors are reviewed and evaluated according to explicit criteria and rated according to their performance and cost.
> Negotiation. Vendor(s) discussions are undertaken and a contract is agreed on.

These stages will be undertaken on the procurement of a turnkey system which includes hardware, software, and support; on the hiring of a contractor to prepare and install the new system; and on the purchase of hardware by the agency/library design team.

The technical specifications should have been drawn up and completed as part of the system design document. These specifications often take the form of a general description of the components needed to meet the requirements, as opposed to a shopping list of specific brands, model numbers, and quantities. The vendor is thus allowed to suggest the best of what is available to meet the specifications. Markuson and her collaborators provided guidelines for preparing hardware specifications.[6]

1. Develop specifications for each type of equipment required
   - Input equipment
   - Computer equipment
   - Output equipment
2. Input equipment specifications should include
   - Character set and encoding characteristics
   - Operating specifications, e.g., ease of operations
   - Reliability of operation
   - Error detection and correction requirements
   - Throughput rates, i.e., speed
   - Display and/or printing requirements
   - Environmental characteristics, e.g., size, noise of operation, portability, etc.
   - Maintenance and training provisions
3. Computer equipment specifications should include
   - Core storage and secondary storage characteristics
   - Data manipulation capabilities
   - Throughput requirements
   - Input readers required, e.g., paper tape readers, and other special peripheral gear
4. Output specifications should include
   - Printing capabilities needed, e.g., upper and lower case
   - Output form handling capabilities
   - Legibility specifications for printing and/or displays
   - Throughput rates
   - Maintenance provisions

Examples of these kinds of specifications were offered at the 1974 clinic on minicomputer applications in libraries. The University of Chicago example was for a front-end minicomputer to serve as a data

[4] Stanley J. Swihart and Beryl F. Hefley, *Computer Systems in the Library: A Handbook for Managers and Designers* (Los Angeles: Melville Publishing Co., 1973), p. 251.

[6] Markuson et al., *Guidelines for Library Automation*, p. 53.

concentrator and high-speed interface to a host (IBM 370/168). The specifications included the following.[7]

1. Processor speed — sufficient to drive the estimated mix of terminals
2. Disk storage — sufficiently large to include software plus certain files
3. Tape drives — two, to log all transactions
4. Console — operator communications and programming tool
5. Communications interfaces — high speed to the computation center, a mix of speeds for the terminals
6. System software — disk oriented, with assemblers or compilers and a communications package
7. Service — to be locally available and reliable

The University of Minnesota Bio-Medical Library specifications for the processor for its minicomputer configuration contained these requirements:[8]

1. CPU must be 8-bit byte-oriented with main memory addressable by byte location and preferred word size a multiple of 8 bits
2. Either explicit character manipulation instructions or some reasonable method of effecting these within the available instruction set
3. Multilevel indirect addressing and indexing or their functional equivalents are required
4. Multilevel indexing is desirable but not required
5. Main memory must be incrementable to at least 64K bytes
6. Direct memory access required
7. Real-time clock required
8. Hardware multiply/divide required
9. Power fail/automatic restart required
10. Memory protection required
11. Operator console keyboard/printer with 30 cps speed required.

One of the best technical specifications ever prepared as part of an RFP was issued by the Library of Congress early in 1977 for the procurement of several minicomputer systems.[9] The system specifications and the weighting for the technical evaluation are presented in Appendix B. The RFP was accompanied by project descriptions for each application area. This one is certainly a well-written model for other libraries to follow.

REVIEW OF HARDWARE/SOFTWARE

Ultimately, somewhere along the flow of events, whatever the method followed, the systems team will have to consider and evaluate specific manufacturer's models, piece by piece. As a background for this procedure, and to provide a common ground for interpretating the proposals, the main components considered in drawing up the five classes of minicomputer systems described in Chapter Three will be reviewed briefly. These descriptions represent a range of what is available in each area. The main characteristics or elements of each component are reviewed. Sample prices or price ranges are given only as a basis for comparison. There is no attempt to specify model names and numbers or precise costs, because the minicomputer industry is in such a state of flux.[10]

A study of minicomputer prices from 1972 to 1975 shows that prices are dropping (Table 20).[11]

TABLE 20—Cost Comparison Between 1972 and 1975

Unit	1972	1975
CPU with 2K memory	$ 2,500	$ 650
4K memory	2,200	550
Chassis	300	100
Power supply	400	375
Control panel	225	275
DMA	300	Included
Power failure restart	350	Included
Teleprinter interface	150	150
Real-time clock	350	Included
Autoload	400	50
16-bit digital I/O	500	500
Paper tape reader/punch	5,800	5,600
Moving head disk	13,000	12,000
Floppy disk (dual)	NA	4,300
Printer	5,500	4,950
	$31,925	$25,200

Technological advances cause changes. The sophistication of a device can increase while the price remains the same or even increases. Prices must be studied carefully for other factors. Some prices are quoted for OEM buyers. These are stripped units with no cabinet, power supply, controller, etc., which are to be incorpo-

[10] Withington predicted advances in computers and included price forecasts to 1985. This included minicomputer components and peripherals — both for state-of-the-art technology and predicted technological developments; see Frederick G. Withington, "Beyond 1974: A Technological Forecast," *Datamation* 21 (January 1975): 54–73.

[11] Marty B. Jarosz, "Minicomputers — Microcomputers — Peripherals; What Are the Real Cost Hang-Ups?" *Mini-Micro Systems* 9 (May 1976): 82.

rated into larger equipment or systems. Prices for end users are higher, because they need complete units ready to use. Some prices are for "packages" or "systems" that include several components with no choice of model or features. Some prices for peripherals do not include the controller, which must be purchased as a separate piece of equipment. Sometimes the controller is part of the larger CPU system, which means that the I/O device would not work on a different manufacturer's CPU. The prices of a major manufacturer can be somewhat higher than those of independent component manufacturers, especially in the area of peripherals.

CPU

The CPU is the most difficult to describe and evaluate. The main elements used to describe the processor are fairly standard, but listing them does not tell the whole story. Note that the manufacturer of each of the following CPUs uses different characteristics to describe it.[12]

Manufacturer 1
Memory technology = core
Memory size (bytes) = 8–32K
Word size (bits) = 16
Cycle time (μs) = 1.2/word
Microprogrammed = Yes

Manufacturer 2
Memory size (byte) = 4–16K
Word size (bits) = 8
Cycle speed (μs) = 1.6
Transmission code = any 7–11 bit code
Maximum I/O devices = 16

Manufacturer 3
Main memory = 10–110 (kc)
Character size = 6 bits
Addressable registers = 3/partition, except common
Cycle time = 3.3 (μs)
No. of I/O channels
 1 slow speed/user partition
 1 high-speed (FAC)
Maximum devices/channels = 10

Manufacturer 4
Memory size = 12–24K
Word size = 24 bits
Maximun I/O channels = 8

Manufacturer 5
Cycle speed (MHz) = 1
Storage technology = MOS
Main memory capacity = 32–80 (Kb)

Manufacturer 6
No. of registers = 20+ implicit register
Memory size (wds) = to 64K (48K available to user)
Bits/word = 8
Parity/Protect = both
Cycle time (μs) = 1.6
Paging = yes
ROM Control memory
Instructions
 Number = 91
 Double precision = yes
 (Hardware) multiply/divide = NA
  floating point = NA
 Stack manipulation = yes
 Priority interrupt = 10 levels

Even with products of a single manufacturer the comparison is difficult. For example, the IBM 370 is known as the latest in large-scale computers. However, 370 is a series number, and a second number identifies the model. At the top of the 370 series, for example, is the 370/168. At the other end of the series, the 370/115 is listed as the minicomputer. The Digital Equipment Company manufactures a minicomputer series called PDP–11. The size and power of this series varies from the PDP11/04 (4K memory) to the PDP11/70 (128K memory). One manual listed the base price of the PDP11/04 as $2,995 and the base price of the PDP11/70 as $54,600.

Sometimes model numbers for a series are based on software alone. For example the General Automation data management DM200 series (220, 230, 240, and 250) all use the same hardware; they differ in their software:[13]

220—Remote job entry
230—Standalone batch system using disk monitor operating system (DMS)
240—Foreground / background (communications / batch) using communications monitor system (CMS)
250—Time-sharing and batch using time-sharing operating system (TSO)

Because of the wide variety of CPUs, it is difficult to state benchmark prices by categories. In fact, price is not always indicative of capability. A General Automation DM 230 standalone batch system was compared to "competitive systems," ranging in price from $47,650 to $82,595 (Table 21).[14] "... It is difficult to be sure that we are comparing apples to apples, since the configurations shown vary in disc storage capacity, basic system components, and card/line printer ratings."

[12] *Auerbach Buyers' Guide to ... Business Minicomputer Systems, Winter 1976–77* (Pennsauken, N.J.: Auerbach Publishers, 1977), pp. 36, 70, 79, 110, 262, 346.
[13] Ibid., pp. 121–2.
[14] Ibid., p. 122.

Table 21—Comparison of "Competitive Systems"

Configuration	Main Memory	Mass Storage	I/O Devices	Price Mid 1975
General Automation DM230	32K bytes	20M bytes disk storage	TTY, line printer (600 lpm), card reader (400 cpm)	$47,650
DEC Datasystem 356	32K bytes	40M bytes disk storage	TTY, line printer (300 lpm)	$61,345
Hewlett-Packard M260	32K bytes	23.5 bytes disk storage	Paper tape input, mag tape device, TTY, line printer (200 lpm)	$79,200
Singer System Ten	30K bytes	20M bytes disk storage	Workstation, line printer (450 lpm)	$82,595
Eclipse C/300	96K bytes	10M bytes disk storage	Console, CRT, mag tape device, 60 lpm printer, 4-line async multiplexor	$77,400

The five classes of minicomputers put together in Chapter Three as sample systems can be priced as a basis of comparison (Table 22). The prices that follow are for end-user systems and are on the high end of the price scale. The price for the processor is for the largest end of the main memory range and includes the CPU, main memory, I/O control, communications control, chassis, power source, control panel (or console), support software, and operating system. It does not include a compiler.

Table 22—Costs of the Five Classes of Minicomputer Systems

Price	Class	Memory Size	Category
$6000-$7000	I	(4K)	Intelligent terminal (Data Collection)
$15,000	II	(32K)	Simple executive monitor or single batch general application
$30,000	III	(64K)	Single or multiple batch with general applications including sorting
$70,000	IV	(128K)	Interactive single application for multiple online users
$85,000	V	(64K)	Time-sharing interactive system with multiple applications for multiple online users

Taking these as base figures, the cost of the various peripheral and software packages to be used can be added for a total system price.

Peripherals

The peripherals chosen to fill out the hardware configuration deserve special consideration. Not only do they perform the system interface to the user and thereby influence the efficacy of the system, they can involve as much as 90 percent of the total cost (see Table 20) of the hardware. Also, the dramatic price drops found in processors have not occurred in the area of peripherals.

In the early days of the minicomputer, most peripherals used were existing ones designed originally for large-scale computers. The miniperipheral market has now developed, and there are many choices for most devices. There are three sources for peripherals: the minicomputer (processor) manufacturer, the OEM manufacturer who sells the peripheral without interface, and the independent manufacturer specializing in complete plug-compatible peripheral systems.

As *Modern Data* pointed out:[15]

> The safest and easiest way to buy a peripheral is from the mini manufacturer. The minimaker has designed, tested, and fabricated interface logic and diagnostic/ debug software to ensure trouble-free mating of the peripheral with the mini. However, since the mini manufacturer usually sells only to his base, production is limited and prices tend to be higher than the other two alternatives.
>
> Independent miniperipheral manufacturers/suppliers are the second alternative. These manufacturers can either manufacture their own complete peripheral sub-system or they can buy from an OEM manufacturer and provide a specialized interface for certain mini models. Most of these manufacturers have a high degree of flexibility since they are not locked into a specific make or model, and they are generally less expensive than mini manufacturers because of high volumes in certain peripherals.
>
> The third alternative is for the do-it-yourselfer who likes to design his own hardware and software interfaces. The peripheral can be purchased from an OEM manufacturer and the controller from a variety of controller manufacturers for the lowest price of the three alternatives.

The advertisements for peripherals manufactured by independents all emphasize which mini model they are compatible with. Industry magazines prepare survey articles and include charts that show which independent's device fits which minicomputer.

[15] "Peripherals Make the Mini; *Modern Data's* Annual Survey of Plug-Compatible Miniperipherals," *Modern Data* 8 (December 1975): 34.

Another facet of the peripheral market is the "IBM-equivalent" or "IBM-standard" product. Some peripherals are designed to replace an IBM device in such a way that the processor and software are "ignorant" of the substitution. For example, disk cartridge systems are presented as equivalent to the IBM 2315 or 5440, and disk packs are described as equivalent to IBM 2314 or 3330 systems.

The point has been made that peripherals are expensive; a high percentage of the cost of the peripheral system is for the interface. Julinssen compiled a table that illustrated the proportion of the cost of the interface to the price of the device (Table 23).[16]

TABLE 23—Comparison of Costs of Peripheral Devices and Their Interfaces

Peripheral Device	Peripheral Price ($K)	Peripheral Interface Price ($K)
TI 3330 Moving Head Disk	20	14
TI Cartridge Moving Head Disk	5.1	3.3
TI Magnetic Tape	6	2.5
DEC Cartridge Moving Head Disk	5.1	5.9
DEC Magnetic Tape	7.5	3.2
AED Floppy Disk	0.75	1.8
Shugard Floppy Disk	0.75	1.6
Sykes Cassette (RS232)	0.6	1.3
Sykes Cassette (Minicomputer Interface)	0.06	1.9

Some independent manufacturers supply interfaces designed specifically for certain device models and miniprocessors. Some firms do custom interfaces on a demand basis.

It should be pointed out that add-on/add-in memory modules are often considered peripherals.[17] They can be offered by the processor manufacturer or an independent vendor. They are used to enhance, augment, or replace existing memory within the limits of the CPU and software.

Mass Storage Devices

There are two basic types of mass storage: sequential and direct access. The sequential devices are usually slower than direct access ones, but they are simpler. They run on smaller, less sophisticated (thus less expensive) hardware and software. Sequential media vary from paper tape and punch cards to magnetic tapes (both cassette type and industry-standard).

The main characteristics of sequential media are speed and ease of use. Capacity does not enter in with cards (except for capacity of card hoppers) but can be a factor with lengths of tape. The data transfer rates determine the price of a device. The rates for reading and punching vary for paper tapes and punch cards, but magnetic tape read and write rates are the same. For all tape devices the speed can vary with the power of the tape drive; fast forward or rewind speeds also can vary and affect system efficiency. Tables 24–28 show the costs of various mass storage devices.

Paper tape and punch card devices.

TABLE 24—Paper Tape (Perforated) Devices (Five-, Six-, or Eight-Channel Tape)

Category	Speed (characters per second)	Price
Reader	Slow: up to 100	$1,600 plus $1,000 controller
	Medium: 100-300	$1,800 plus $4,000 to $8,000 controller
	High: greater than 300	
Punch	Slow: up to 60	$3,000 to $9,900
	Medium: 61–120	$5,500 plus $4,000 to $8,000 controller
Reader/Punch		$4,200

Note: The prices are only samples randomly chosen. The controller may be part of the mainframe system, and the manufacturer's unit can be used only on its equipment. There may be a separate controller, which must be purchased separately, or the device may have the controller installed in it and included in the price.

TABLE 25—Punch Card Devices (80-Column)

Category	Speed (cards per minute)		Price
Reader	Slow:	up to 300	$4,000 to $6,000 with controller
	Medium:	301–799	Up to $10,000 with controller
	High:	800–1400	$10,000 to $15,000 with controller
Punch	Slow:	up to 70	$1,900 plus controller ($750)
	Medium:	71–149	$9,000 to $12,000
	High:	150–300	$10,000 to $30,000
Reader/Punch	Read 300, punch 60		$9,500 plus controller ($1,900)
Multipurpose unit (can include sorter)	Read 300, punch 60		$11,400 plus controller ($2,100)

Magnetic tape cassettes and cartridges. The tape cassette is the simplest magnetic tape device. It looks like an audio cassette and was introduced by Philips. The cartridge was developed by IBM; it has wider

[16] J. Egil Juliussen, "The Cost Outlook for Peripheral Controllers," *Mini-Micro Systems* 10 (January 1977): 64.
[17] "Peripherals Make the Mini," p. 36.

tape (therefore more tracks) and more capacity. An article in *Modern Data* compared the two forms (Tables 26, 27).[18]

TABLE 26—Comparison of Magnetic Tape Cassettes and Cartridges

	Cassette	Cartridge
Price of drive with read/ write and motor control electronics	$450	$700
Price of a unit (cassette or cartridge)	$ 8	$ 20
Average capacity of media	5.4M bits (2 tracks)	23M bits (4 tracks)
Average transfer rate	8K bps	48K bps

TABLE 27—Tape Cassettes

Read/Write Speed	Rewind Speed	Density	Price
Ranges from 0 to 30 ips	20 to 140 ips	120 to 1000 bpi	$1,200 to $2,700 single drive $2,300 to $3,400 dual drive

Industry-standard magnetic tape. Magnetic tape on open reels of 7½- or 10-inch diameter is the common tape for both large-scale computers and minicomputers. The tapes have seven or nine tracks and are recorded at 800 or 1600 bits per inch (bpi). The read and write speeds range from 10 to about 75 inches per second, or 10–100 thousand bits per second (10–100 KB). Some devices come as clusters composed of multiple drives and controller units. Prices vary according to combinations of variables present (Table 28).

TABLE 28—Industry-Standard Tape Drives

Tracks	Density	Read/Write Speed	No. of Drives	Price
7	800 bpi	12.5 ips	1	$ 7,950
9	800 bpi	12.5 ips	1	7,950
9	800 bpi	12.5 ips	1	8,255
9	800 bpi	10 KB	1	8,600
9	800 bpi	96 KB	1	20,400
9	800 bpi	20 K BPS	1	7,850
9	800 bpi	40 K BPS	1	10,500
9	800 bpi	80 K BPS	1	13,000
9	1600 bpi	20 K BPS	1	17,300
9	1600 bpi	40 K BPS	1	21,900
9	1600 bpi	80 K BPS	1	26,700
9	800 bpi	18 K B	3	26,960
9	800 bpi	18 K B	4	32,160
9	800 bpi	37.5 ips	1	16,000
9	800 bpi	37.5 ips	+ 2nd unit	10,250

Direct access storage devices. Direct access mass storage uses disks (diskette or floppy disk, fixed-head disk platter, movable-head disk cartridge, movable-head disk pack). Floppies are better compared to tape cassettes than to the large disk devices.[19] The price of the drive is about the same as the tape cartridge drive; the floppy itself costs the same as a tape cassette and its capacity is smaller than that of a cassette or cartridge. The transfer rate is significantly faster for the floppy:

Cassette	8K bps
Cartridge	48K bps
Floppy	250K bps

Some floppies are compatible with IBM equipment, and some are noncompatible (either in the data format or the plug for the drive); there are single; double density floppies.[20]

Each device comes with a drive and a controller. The units come in single, dual, or triple drives:

Single drive and controller	$2,800 to $4,500
Dual drive and controller	$3,750 to $6,000
Triple drive and controller	$6,200 to $8,000

Fixed-head disks. The fixed-head or head-per-track disk is the fastest but has the most expensive per unit capacity. The total capacity available is less than that of a movable-head disk. A unit with a 512K-byte capacity costs $10,880. One movable disk pack has a 20M-byte capacity and costs $9,500.

Disk cartridges. A disk cartridge is a movable-head disk in a unit of one or two platters. Single disk cartridges are removable which means the files can be transferred physically from system to system. Double disk cartridges are often combinations of one fixed disk and one removable disk. A number of characteristics can be used to describe disk cartridges, but only a few are significant:[21]

Drive capacity: storage capacity in megabytes using unformated data.

Average access time: speed in positioning to get ready to read or write (expressed in milliseconds).

Transfer rate: read or write speed (expressed in kilobytes per second).

TABLE 29—Disk Cartridges

	Capacity	Price	Access Time	Transfer Rate
Low Capacity	2.5M bytes	\$5,950 to \$11,000	45–90 μs	180–312K bytes/s
Medium Capacity	4.8 to 6.25M bytes	\$6,000 to \$14,000	42–90 μs	150–312K bytes/s
High Capacity	9.6 to 12.5M bytes	\$7,500 to \$12,500	38–90 μs	181–312K bytes/s
High-Density (3000–4680 bpi), High Capacity	25 to 26M bytes	\$15,000 to \$24,500	33 μs	312–937K bytes/s

Bit density: the common density is 2200 bits per inch, but some newer disks have densities of more than 4000 bpi.

Price: prices include the drive and the controller.

Prices are related to the capacity of the cartridges (Table 29). The capacities range from 2.5M bytes to 10M bytes with several exceptionally larger units available.

Disk packs. The disk pack is the largest capacity unit. Within a unit there can be 10 or more platters that are read by a movable head drive. Some disk packs add a second drive. The same elements are important for a disk pack as for a disk cartridge: capacity, access time, and transfer rate. Table 30 compares prices of various disk pack units.

TABLE 30—Disk Packs

Capacity	Number of Drives	Price with Controller
20M bytes to 30M bytes	one	\$11,500 to \$18,500
	add second drive	\$10,000 to \$15,300
40M bytes	one	\$35,000 to \$40,000
80M bytes	one	\$28,000 to \$30,000
	add second drive	\$15,000
95M bytes to 175M bytes	dual	\$58,000 to \$75,000

Man/Machine Interface Devices

Man/machine interface devices output and input information in human-understandable form. These devices differ significantly in input/output capabilities. Some are input only, others output only, and still others handle both input and output. Some are hardcopy, some display, and some both.

Punch card readers and paper tape readers are input only devices and were discussed under mass storage devices. Printers are the most common output only devices.

Printers. Printers vary according to several characteristics:

Speed — ranges from 10 characters per second to 18,000 lines per minute

Price — varies from approximately \$100 to \$310,000

Method — impact or nonimpact

Mode — character at a time in a serial format or line at a time in a parallel format

Character images — shaped or dot matrix

Character sets — 64 (upper case), 96 (upper and lower case) 128 (upper and lower case plus special characters)

Type of paper and paper feed — heat-sensitive paper, friction feed roller or sprocket feed roller — these all affect the ability to print special forms and/or multiple copies.

Printer units contain an interface to the computer, a power supply, and control electronics (sometimes including a buffer).

Modern Data prepared a summary of typical printer prices at the end of 1975 (Table 31).[22] It gives an overview of the printer market.
